

Sweave User Manual

Friedrich Leisch and R-core

March 5, 2019

1 Introduction

Sweave provides a flexible framework for mixing text and R code for automatic document generation. A single source file contains both documentation text and R code, which are then *woven* into a final document containing

- the documentation text together with
- the R code and/or
- the output of the code (text, graphs)

This allows the re-generation of a report if the input data change and documents the code to reproduce the analysis in the same file that contains the report. The R code of the complete analysis is embedded into a L^AT_EX document¹ using the `noweb` syntax (Ramsey, 1998) which is usually used for literate programming Knuth (1984). Hence, the full power of L^AT_EX (for high-quality typesetting) and R (for data analysis) can be used simultaneously. See Leisch (2002) and references therein for more general thoughts on dynamic report generation and pointers to other systems.

Sweave uses a modular concept using different drivers for the actual translations. Obviously different drivers are needed for different text markup languages (L^AT_EX, HTML, ...). Several packages on CRAN provide support for other word processing systems (see Appendix A).

2 Noweb files

`noweb` (Ramsey, 1998) is a simple literate-programming tool which allows combining program source code and the corresponding documentation into a single file. A `noweb` file is a simple text file which consists of a sequence of code and documentation segments, called *chunks*:

Documentation chunks start with a line that has an at sign (`@`) as first character, followed by a space or newline character. The rest of this line is a comment and ignored. Typically documentation chunks will contain text in a markup language like L^AT_EX. The chunk continues until a new code or documentation chunk is started: note that Sweave does not interpret the contents of documentation chunks, and so will identify chunk indicators even inside L^AT_EX verbatim environments.

Code chunks start with `<<options>>=` at the beginning of a line; again the rest of the line is a comment and ignored.

The default for the first chunk is documentation.

In the simplest usage of `noweb`, the options (if present) of the code chunks give the names of source code files, and the tool `notangle` can be used to extract the code chunks from the

¹<http://www.ctan.org>

noweb file. Multiple code chunks can have the same name, the corresponding code chunks are the concatenated when the source code is extracted. **noweb** has some additional mechanisms to cross-reference code chunks (the `[[...]]` operator, etc.), Sweave does currently not use nor support these features, so they are not described here.

3 Sweave files

3.1 A simple example

Sweave source files are **noweb** files with some additional syntax that allows some additional control over the final output. Traditional **noweb** files have the extension ‘.nw’, which is also fine for Sweave files (and fully supported by the software). Additionally, Sweave currently recognizes files with extensions ‘.rnw’, ‘.Rnw’, ‘.snw’ and ‘.Snw’ to directly indicate a **noweb** file with Sweave extensions. We will use ‘.Rnw’ throughout this document.

A minimal Sweave file is shown in Figure 1, which contains two code chunks embedded in a simple L^AT_EX document. Running

```
> rnwfile <- system.file("Sweave", "example-1.Rnw", package = "utils")
> Sweave(rnwfile)
```

Writing to file example-1.tex

Processing code chunks with options ...

```
1 : echo keep.source term verbatim (example-1.Rnw:13)
2 : echo keep.source (label = boxp, example-1.Rnw:22)
3 : keep.source term verbatim pdf (example-1.Rnw:27)
```

You can now run (pdf)latex on 'example-1.tex'

translates this into the L^AT_EX document shown in Figures 2 and 3. The latter can also be created directly from within R using

```
> tools::texi2pdf("example-1.tex")
```

The first difference between ‘example-1.Rnw’ and ‘example-1.tex’ is that the L^AT_EX style file ‘Sweave.sty’ is automatically loaded, which provides environments for typesetting R input and output (the L^AT_EX environments `Sinput` and `Soutput`). Otherwise, the documentation chunks are copied without any modification from ‘example-1.Rnw’ to ‘example-1.tex’.

The real work of Sweave is done on the code chunks: The first code chunk has no name, hence the default behavior of Sweave is used, which transfers both the R commands and their respective output to the L^AT_EX file, embedded in `Sinput` and `Soutput` environments, respectively.

The second code chunk shows one of the Sweave extension to the **noweb** syntax: Code chunk names can be used to pass options to Sweave which control the final output.

- The chunk is marked as a figure chunk (`fig=TRUE`) such that Sweave creates (by default) a PDF file of the plot created by the commands in the chunk. Furthermore, a `\includegraphics{example-1-002}` statement is inserted into the L^AT_EX file (details on the choice of file names for figures follow later in this manual).
- Option `echo=FALSE` indicates that the R input should not be included in the final document (no `Sinput` environment).

```

March 5, 2019

In this example we embed parts of the examples from the `kruskal.test` help page into a $\text{\LaTeX}$ document:

```
> data(airquality, package="datasets")
> library("stats")
> kruskal.test(Ozone ~ Month, data = airquality)
```

Kruskal-Wallis rank sum test

data: Ozone by Month

Kruskal-Wallis chi-squared = 29.267, df = 4, p-value = 6.901e-06

which shows that the location parameter of the Ozone distribution varies significantly from month to month. Finally, we include a boxplot of the data, using

```
> boxplot(Ozone ~ Month, data = airquality)
```

Figure 3: The final document is created by running `pdflatex` on ‘example-1.tex’.

3.2 Sweave options

Options control how code chunks and their output (text, figures) are transferred from the ‘.Rnw’ file to the ‘.tex’ file. All options have the form **key=value**, where **value** can be a number, string or logical value. Several options can be specified at once (separated by commas), all options must take a value (which must not contain a comma or equal sign). Logical options can take the values **TRUE**, **FALSE**, **T**, **F** as well as lower-case and capitalized versions of the first two.

In the ‘.Rnw’ file options can be specified either

1. inside the angle brackets at the beginning of a code chunk, modifying the behaviour *only for this chunk*, or
2. anywhere in a documentation chunk using the command

```
\SweaveOpts{opt1=value1, opt2=value2, ..., optN=valueN}
```

which modifies the defaults for the rest of the document, i.e., *all code chunks after the statement*. Hence, an **\SweaveOpts** statement in the preamble of the document sets defaults for all code chunks.

Further, global options can be specified (as a comma-separated list of **key=value** items) in the environment variable **SWEAVE_OPTIONS**, and via the **--options=** flag of R CMD Sweave.

Which options are supported depends on the driver in use. All drivers should at least support the following options (all options appear together with their default value, if any):

split=FALSE: a logical value. If **TRUE**, then the output is distributed over several files, if **FALSE** all output is written to a single file. Details depend on the driver.

label: a text label for the code chunk, which is used for file-name creation when **split=TRUE**. It is also used in the comments added above the chunk when the file is processed by **Rtangle** (provided the **annotate** option is true, as it is by default), and as part of the file names for files generated by figure chunks.

Because labels can be part of file names, they should contain only alphanumeric characters and **#+-_.** (Including **.** can cause confusion with file extensions.)

The first (and only the first) option in a code chunk name can be optionally without a name, then it is taken to be a label. I.e., starting a code chunk with

```
<<hello, split=FALSE>>
```

is the same as

```
<<split=FALSE, label=hello>>
```

but

```
<<split=FALSE, hello>>
```

gives a syntax error. Having an unnamed first argument for labels is needed for **noweb** compatibility. If only **\SweaveOpts** is used for setting options, then Sweave files can be written to be fully compatible with **noweb** (as only file names appear in code chunk names).

Note that **split=TRUE** should **not** be used in package vignettes.

The help pages for **RweaveLatex** and **Rtangle** list the options supported by the default Sweave and Stangle drivers.

Now for the promised details on the file names corresponding to figures. These are of the form **prefix-label.ext**. Here **prefix** can be set by the option **prefix.string**, otherwise is the basename of the output file (which unless specified otherwise is the basename of the input file). **label** is the label of the code chunk if it has one, otherwise the number of

the code chunk in the range 001 to 999. `ext` is the appropriate extension for the type of graphics, e.g. `pdf`, `eps`, So for the `'example-1.Rnw'` file, the PDF version of the boxplot is `'example-1-002.pdf'`, since it is the second code chunk in the document. Note that if `prefix.string` is used it can specify a directory as part of the prefix, so that for example if `\SweaveOpts{prefix.string=figures/fig}`, the auto-generated figures will be placed in sub-directory `figures`: the Sweave document should arrange to create this before use.

3.3 Using multiple input files

L^AT_EX files can include others via `\input{}` commands. These can also be used in Sweave files, but the included files will be included by L^AT_EX and are not processed by Sweave. The equivalent if you want the included files to be processed is the `\SweaveInput{}` command.

Included files should use the same Sweave syntax (see below) and encoding as the main file.

3.4 Using scalars in text

There is limited support for using the values of R objects in text chunks. Any occurrence of `\Sexpr{expr}` is replaced by the string resulting from coercing the value of the expression `expr` to a character vector; only the first element of this vector is used. E.g., `3` will be replaced by the string `'3'` (without any quotes).

The expression is evaluated in the same environment as the code chunks, hence one can access all objects defined in the code chunks which have appeared before the expression and were evaluated. The expression may contain any valid R code, only braces (`{ }`) are not allowed. (This is not really a limitation because more complicated computations can be easily done in a hidden code chunk and the result then be used inside a `\Sexpr`.)

3.5 Code chunk reuse

Named code chunks can be reused in other code chunks following later in the document. Consider the simple example

```
<<a>>=
x <- 10
@

<<b>>=
x + y
@

<<c>>=
<<a>>
y <- 20
<<b>>
```

which is equivalent to defining the last code chunk as

```
<<c>>=
x <- 10
y <- 20
x + y
@
```

The chunk reference operator `<<>>` takes only the name of the chunk as its argument: no additional Sweave options are allowed. It has to occur at the beginning of a line.

References to unknown chunk names are omitted, with a warning.

3.6 Syntax definition

So far we have only talked about Sweave files using `noweb` syntax (which is the default). However, Sweave allows the user to redefine the syntax marking documentation and code chunks, using scalars in text or reuse code chunks.

```
\documentclass[a4paper]{article}

\title{Sweave Example 1}
\author{Friedrich Leisch}

\begin{document}

\maketitle

In this example we embed parts of the examples from the
\texttt{kruskal.test} help page into a \LaTeX{} document:

\begin{Scode}{}
data(airquality, package="datasets")
library("stats")
kruskal.test(Ozone ~ Month, data = airquality)
\end{Scode}
which shows that the location parameter of the Ozone
distribution varies significantly from month to month. Finally, we
include a boxplot of the data, using
%% want an eval=FALSE case and referencing a previous chunk:
\begin{Scode}{boxp, eval=FALSE}
boxplot(Ozone ~ Month, data = airquality)
\end{Scode}

\begin{center}
\begin{Scode}{fig=TRUE,echo=FALSE}
library("graphics")
\Scoderef{boxp}
\end{Scode}
\end{center}

\end{document}
```

Figure 4: An Sweave file using L^AT_EX syntax: ‘example-1.Stex’.

Figure 4 shows the example from Figure 1 using the `SweaveSyntaxLatex` definition. It can be created using

```
> SweaveSyntConv(rnwfile, SweaveSyntaxLatex)
```

Wrote file example-1.Stex

Code chunks are now enclosed in `Scode` environments, code chunk reuse is performed using `\Scoderef{chunkname}`. All other operators are the same as in the `noweb`-style syntax.

Which syntax is used for a document is determined by the extension of the input file, files with extension² ‘.Rtex’ or ‘.Stex’ are assumed to follow the L^AT_EX-style syntax. Alternatively the syntax can be changed at any point within the document using the commands

²or the lowercase versions, for convenience on case-insensitive file systems.

```
\SweaveSyntax{\SweaveSyntaxLatex}
```

or

```
\SweaveSyntax{\SweaveSyntaxNoweb}
```

at the beginning of a line within a documentation chunk. Syntax definitions are simply lists of regular expression for several Sweave commands: see the two default definitions mentioned above for examples. (More detailed instructions will follow once the API has stabilized).

3.7 Encoding

L^AT_EX documents are traditionally written entirely in ASCII, using L^AT_EX escapes such as `\'e` for accented characters. This can be inconvenient when writing a non-English document, and an alternative input encoding can be selected by using a statement such as

```
\usepackage[latin1]{inputenc}
```

in the document's preamble, to tell L^AT_EX to translate the input to its own escapes. There is a wide range of input encodings which are supported, at least partially, and the more recent L^AT_EX package `inputenx` supports more. Other encodings commonly encountered in Sweave documents are `latin9`, `utf8` and `ansinew` (the CP1252 codepage on Windows). Greater coverage³ of UTF-8 can be obtained by

```
\usepackage[utf8]{inputenx} \input{ix-utf8enc.dfu}
```

As from R 3.1.0, the UTF-8 encoding is handled preferentially to other encodings. Whereas Sweave will convert R code to the local encoding in general, it leaves UTF-8 code in that encoding, and outputs in that encoding as well. Besides the declaration scheme above, a UTF-8 encoding may be obtained by the L^AT_EX comment

```
%\SweaveUTF8
```

The previous paragraphs covered the documentation sections, but what of the code sections where L^AT_EX escapes cannot be used? The first piece of advice is to use only ASCII code sections as anything else will reduce the portability of your document. But R code can be included if in the input encoding declared in the preamble.

The next complication is inclusions: the final vignette may well include R output, L^AT_EX or other Sweave files *via* `\input{}` and `\SweaveInput{}` lines, a bibliography and figures. It is the user's responsibility that the text inclusions are covered by the declared input encoding. L^AT_EX allows the input encoding to be changed by

```
\inputencoding{something}
```

statements: these may not work well in Sweave processing. Since `\usepackage[latin1]{inputenc}` is typically not legal L^AT_EX code in an included file, it is easiest to declare the encoding to Sweave using the `%\SweaveUTF8` comment.

It is all too easy for BiBTeX to pick up UTF-8-encoded references for a Latin-1 document, or *vice versa*.

R output is again to a large extent under the user's control. If a Latin-1 Sweave document is processed by R running a Latin-1 locale or a UTF-8 document is processed in a UTF-8 locale, the only problems which are likely to arise are from handling data in another encoding, but it may be necessary to declare the document's encoding to cover the R output which is generated even if the document is itself ASCII. One common problem is the quotes produced by `\sQuote()` and `\dQuote()`: these will be in UTF-8 when R is run in a UTF-8 locale,

³including Eastern European, Greek and Hebrew letters.

and will be in CP1252 when Sweave is run from `Rgui.exe` on Windows. Two possible solutions are to suppress fancy quotes by `options(useFancyQuotes=FALSE)` or to force UTF-8 by `options(useFancyQuotes="UTF-8")`.

The encoding of figures is not usually an issue as they are either bitmaps or include encoding information: it may be necessary to use the `pdf.encoding` Sweave option to set the `pdf()` device up appropriately.

4 Tangling and weaving

The user front-ends of the Sweave system are the two R functions `Stangle()` and `Sweave()`, both are contained in package `utils`. `Stangle` can be used to extract only the code chunks from an `.Rnw` file and write to one or several files. `Sweave()` runs the code chunks through R and replaces them with the respective input and/or output. `Stangle` is actually just a wrapper function for `Sweave`, which uses a tangling instead of a weaving driver by default. See

```
> help("Sweave")
```

for more details and arguments of the functions.

4.1 The RweaveLatex driver

This driver transforms `.Rnw` files with $\text{\LaTeX}$ documentation chunks and R code chunks to proper $\text{\LaTeX}$ files (for typesetting both with standard `latex` or `pdflatex`), see

```
> help("RweaveLatex")
```

for details, including the supported options.

4.1.1 Writing to separate files

If `split` is set to `TRUE`, then all text corresponding to code chunks (the `Sinput` and `Soutput` environments) is written to separate files. The file names are of form `'prefix.string-label.tex'`, if several code chunks have the same label, their outputs are concatenated. If a code chunk has no label, then the number of the chunk is used instead. The same naming scheme applies to figures. You do need to ensure that the file names generated are valid and not so long that there are not regarded as the same by your OS (some file systems only recognize 13 characters).

4.1.2 $\text{\LaTeX}$ style file

The driver automatically inserts a `\usepackage{Sweave.sty}` command as last line before the `\begin{document}` statement of the final $\text{\LaTeX}$ file if no `\usepackage{Sweave}` is found in the Sweave source file. This style file defines the environments `Sinput` and `Soutput` for typesetting code chunks. If you do not want to include the standard style file, e.g., because you have your own definitions for `Sinput` and `Soutput` environments in a different place, simply insert a comment like

```
% \usepackage{Sweave}
```

in the preamble of your latex file, this will prevent automatic insertion of the line.

4.1.3 Figure sizes

`'Sweave.sty'` sets the default $\text{\LaTeX}$ figure width (which is independent of the size of the generated EPS or PDF files). The current default is

```
\setkeys{Gin}{width=0.8\textwidth}
```

if you want to use another width for the figures that are automatically generated and included by Sweave, simply add a line similar to the one above *after* `\begin{document}`. If you want no default width for figures insert a `\usepackage[nogin]{Sweave}` in the header of your file. Note that a new graphics device is opened for each figure chunk (one with option `fig=TRUE`), hence all graphical parameters of the `par()` command must be set in each single figure chunk and are forgotten after the respective chunk (because the device is closed when leaving the chunk).

Attention: One thing that gets easily confused are the width/height parameters of the R graphics devices and the corresponding arguments to the L^AT_EX `\includegraphics` command. The Sweave options `width` and `height` are passed to the R graphics devices, and hence affect the default size of the produced EPS and PDF files. They do not affect the size of figures in the document, by default they will always be 80% of the current text width. Use `\setkeys{Gin}` to modify figure sizes or use explicit `\includegraphics` commands in combination with the Sweave option `include=FALSE`.

4.1.4 Prompts and text width

By default the driver gets the prompts used for input lines and continuation lines from R's `options()` settings. To set new prompts use something like

```
options(prompt = "MyR> ", continue = "...")
```

see `help(options)` for details. Similarly the output text width is controlled by option `"width"`.

4.1.5 Graphics devices

The default graphics device for `fig=TRUE` chunks is `pdf()`: the standard options `pdf`, `eps`, `png` and `jpg` allow one or more of these to be selected for a particular chunk or (via `\SweaveOpts`) for the whole document. It can be convenient to select PNG for a particular figure chunk by something like `<<figN, fig=TRUE, pdf=FALSE, png=TRUE>>`: `pdflatex` should automatically include the PNG file for that chunk.

You can define your own graphics devices and select one of them by the option `grdevice=my.Swd` where the device function (here `my.Swd`) is defined in a hidden code chunk. For example, we could make use of the `cairo_pdf` device by

```
my.Swd <- function(name, width, height, ...)
  grDevices::cairo_pdf(filename = paste(name, "pdf", sep = "."),
    width = width, height = height)
```

Specialized custom graphics devices may need a customized way to shut them down in place of `graphics.off()`: this can be supplied *via* a companion function `my.Swd.off`, which is called with no arguments.

For a complete example see the file `'src/library/utils/tests/customgraphics.Rnw'` in the R sources.

4.2 The Rtangle driver

This driver can be used to extract R code chunks from a `'Rnw'` file. Code chunks can either be written to one large file or separate files (one for each code chunk). The options `split`, `prefix`, and `prefix.string` have the same defaults and interpretation as for the `RweaveLatex` driver. Use the standard `noweb` command line tool `notangle` if chunks other than R code should be extracted. See

```
> help("Rtangle")
```

for details.

Note that `split=TRUE` rarely makes much sense, as the files produced are often interdependent and need to be run in a particular order, an order which is often not the alphabetical order of the files.

5 Adding Sweave Drivers

Adding drivers is relatively simple by modelling them on⁴ the existing `RweaveLatex` and `Rtangle` drivers.

An Sweave driver is a function of no arguments which should return a list of five functions:

`setup(file, syntax, ...)`: Set up the driver, e.g. open the output file. Its return value is an object which is passed to the next three functions, and can be updated by the next two. The value should be a list, and contain a component `options`, a named list of the default settings for the options needed by `runcode`.

`runcode(object, chunk, options)`: Process a code chunk. Returns a possibly updated object. Argument `chunk` is a character vector, and `options` is a options list for this chunk.

`writedoc(object, chunk)`: Write out a documentation chunk. Returns a possibly updated object.

`finish(object, error)`: Finish up, or clean up if `error` is true.

`checkopts(options)`: Converts/validates `options` given as a named list of character strings.

Note that the `setup` function should have a `...` argument. It will be passed additional arguments from a `Sweave()` call, but in future `Sweave` may itself set options and pass them on the setup function: one such may be the encoding used for the text to be processed.

A Frequently Asked Questions

A.1 How can I get Emacs to automatically recognize files in Sweave format?

Recent versions of ESS (Emacs speaks statistics, <https://ESS.R-project.org/>) automatically recognize files with extension ‘.Rnw’ as Sweave files and turn on the correct modes. Please follow the instructions on the ESS homepage on how to install ESS on your computer.

A.2 Can I run Sweave directly from a shell?

E.g., for writing makefiles it can be useful to run Sweave directly from a shell rather than manually starting R and then running Sweave. This can easily be done using

```
R CMD Sweave file.Rnw
```

A.3 Why does $\LaTeX$ not find my EPS and PDF graphic files when the file name contains a dot?

Sweave uses the standard $\LaTeX$ package `graphicx` to handle graphic files, which automatically chooses the type of file, provided the basename given in the `\includegraphics{}` statement has no extension. Hence, you may run into trouble with graphics handling if the basename of your Sweave file contains dots: ‘foo.Rnw’ is OK, while ‘foo.bar.Rnw’ is not.

A.4 Empty figure chunks give $\LaTeX$ errors.

When a code chunk with `fig=TRUE` does not call any plotting functions, invalid PDF (or EPS) files may be created. Sweave cannot know if the code in a figure chunk actually plotted something or not, so it will try to include the graphics, which is bound to fail.

A.5 Why do R lattice graphics not work?

In recent versions of Sweave they do if they would when run at the command line: some calls (e.g. those inside loops) need to be explicitly `print()`-ed.

A.6 How can I get Black & White lattice graphics?

What is the most elegant way to specify that strip panels are to have transparent backgrounds and graphs are to be in black and white when lattice is being used with Sweave? I would prefer a global option that stays in effect for multiple plots.

Answer by Deepayan Sarkar: I’d do something like this as part of the initialization:

```
<<...>>
library(lattice)
ltheme <- canonical.theme(color = FALSE)      ## in-built B&W theme
ltheme$strip.background$col <- "transparent" ## change strip bg
lattice.options(default.theme = ltheme)      ## set as default
@
```

A.7 Creating several figures from one figure chunk does not work

Consider that you want to create several graphs in a loop similar to

```
<<fig=TRUE>>
for (i in 1:4) plot(rnorm(100)+i)
@
```

This will currently **not** work, because Sweave allows **only one graph** per figure chunk. The simple reason is that Sweave opens a **pdf** device before executing the code and closes it afterwards. If you need to plot in a loop, you have to program it along the lines of

```
<<results=tex,echo=FALSE>>=
for(i in 1:4){
  fname <- paste("myfile", i, ".pdf", sep = "")
  pdf(file = fname, width = 6, height = 6)
  plot(rnorm(100)+i)
  dev.off()
  cat("\\includegraphics{", fname, "}\n\n", sep = "")
}
@
```

A.8 How can I set default `par()` settings for figure chunks?

Because Sweave opens a new device for each graphics file in each figure chunk, using `par()` has only an effect if it is used inside a figure chunk. If you want to use the same settings for a series of figures, it is easier to use a hook function than repeating the same `par()` statement in each figure chunk.

The effect of

```
options(SweaveHooks = list(fig = function() par(bg = "red", fg = "blue")))
```

should be easy to spot.

A.9 How can I change the formatting of R input and output chunks?

Sweave uses the `fancyvrb` package for formatting all R code and text output. `fancyvrb` is a very powerful and flexible package that allows fine control for layouting text in verbatim environments. If you want to change the default layout, simply read the `fancyvrb` documentation and modify the definitions of the `Sinput` and `Soutput` environments in ‘`Sweave.sty`’, respectively.

A.10 How can I change the line length of R input and output?

Sweave respects the usual way of specifying the desired line length in R, namely `options(width)`. E.g., after `options(width = 40)` lines will be formatted to have at most 40 characters (if possible).

A.11 Can I use Sweave for Word files?

Not directly, but package **SWord** provides similar functionality for Microsoft Word on Windows platforms.

A.12 Can I use Sweave for OpenOffice files?

Yes, package **odfWeave** provides functions for using Sweave in combination with OpenOffice Writer rather than $\text{\LaTeX}$.

A.13 Can I use Sweave for HTML files?

Yes, package **R2HTML** provides a driver for using Sweave in combination with HTML rather than $\text{\LaTeX}$.

A.14 After loading package **R2HTML** Sweave doesn't work properly!

Package **R2HTML** registers an Sweave driver for HTML files using the same file extensions as the default **noweb** syntax, and after that its syntax is on the search list before the default syntax. Using

```
options(SweaveSyntax = "SweaveSyntaxNoweb")
```

or calling Sweave like

```
Sweave(..., syntax = "SweaveSyntaxNoweb")
```

ensures the default syntax even after loading package **R2HTML**.
