## slightly modified from the S-PLUS help page for nlminb
# this example minimizes a sum of squares with known solution y
sumsq <- function( x, y) {sum((x-y)^2)}
y <- rep(1,5)
```

```

x0 <- rnorm(length(y))
nlminb(start = x0, sumsq, y = y)
# now use bounds with a y that has some components outside the bounds
y <- c( 0, 2, 0, -2, 0)
nlminb(start = x0, sumsq, lower = -1, upper = 1, y = y)
# try using the gradient
sumsq.g <- function(x, y) 2*(x-y)
nlminb(start = x0, sumsq, sumsq.g,
        lower = -1, upper = 1, y = y)
# now use the hessian, too
sumsq.h <- function(x, y) diag(2, nrow = length(x))
nlminb(start = x0, sumsq, sumsq.g, sumsq.h,
        lower = -1, upper = 1, y = y)

## Description

Determine the nonlinear (weighted) least-squares estimates of the parameters of a nonlinear model.

## Usage

```
nls(formula, data, start, control, algorithm,
```

```
trace, subset, weights, na.action, model,
lower, upper, ...)
```

### Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula      | a nonlinear model <a href="#">formula</a> including variables and parameters. Will be coerced to a formula if necessary.                                                                                                                                                                                                                                                                                                                                                                |
| data         | an optional data frame in which to evaluate the variables in formula and weights. Can also be a list or an environment, but not a matrix.                                                                                                                                                                                                                                                                                                                                               |
| start        | a named list or named numeric vector of starting estimates. When start is missing, a very cheap guess for start is tried (if <code>algorithm != "plinear"</code> ).                                                                                                                                                                                                                                                                                                                     |
| control      | an optional list of control settings. See <a href="#">nls.control</a> for the names of the settable control values and their effect.                                                                                                                                                                                                                                                                                                                                                    |
| algorithm    | character string specifying the algorithm to use. The default algorithm is a Gauss-Newton algorithm. Other possible values are "plinear" for the Golub-Pereyra algorithm for partially linear least-squares models and "port" for the 'nl2sol' algorithm from the Port library – see the references. Can be abbreviated.                                                                                                                                                                |
| trace        | logical value indicating if a trace of the iteration progress should be printed. Default is FALSE. If TRUE the residual (weighted) sum-of-squares and the parameter values are printed at the conclusion of each iteration. When the "plinear" algorithm is used, the conditional estimates of the linear parameters are printed after the nonlinear parameters. When the "port" algorithm is used the objective function value printed is half the residual (weighted) sum-of-squares. |
| subset       | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                                                                                                                                                                               |
| weights      | an optional numeric vector of (fixed) weights. When present, the objective function is weighted least squares.                                                                                                                                                                                                                                                                                                                                                                          |
| na.action    | a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of <a href="#">options</a> , and is <a href="#">na.fail</a> if that is unset. The 'factory-fresh' default is <a href="#">na.omit</a> . Value <a href="#">na.exclude</a> can be useful.                                                                                                                                                                |
| model        | logical. If true, the model frame is returned as part of the object. Default is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                  |
| lower, upper | vectors of lower and upper bounds, replicated to be as long as start. If unspecified, all parameters are assumed to be unconstrained. Bounds can only be used with the "port" algorithm. They are ignored, with a warning, if given for other algorithms.                                                                                                                                                                                                                               |
| ...          | Additional optional arguments. None are used at present.                                                                                                                                                                                                                                                                                                                                                                                                                                |

### Details

An `nls` object is a type of fitted model object. It has methods for the generic functions [anova](#), [coef](#), [confint](#), [deviance](#), [df.residual](#), [fitted](#), [formula](#), [logLik](#), [predict](#), [print](#), [profile](#), [residuals](#), [summary](#), [vcov](#) and [weights](#).

Variables in formula (and weights if not missing) are looked for first in data, then the environment of formula and finally along the search path. Functions in formula are searched for first in the environment of formula and then along the search path.

Arguments `subset` and `na.action` are supported only when all the variables in the formula taken from data are of the same length: other cases give a warning.

Note that the `anova` method does not check that the models are nested: this cannot easily be done automatically, so use with care.

### Value

A list of

|                                   |                                                                                                                                                                                                   |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>m</code>                    | an <code>nlsModel</code> object incorporating the model.                                                                                                                                          |
| <code>data</code>                 | the expression that was passed to <code>nls</code> as the data argument. The actual data values are present in the environment of the <code>m</code> component.                                   |
| <code>call</code>                 | the matched call with several components, notably <code>algorithm</code> .                                                                                                                        |
| <code>na.action</code>            | the <code>"na.action"</code> attribute (if any) of the model frame.                                                                                                                               |
| <code>dataClasses</code>          | the <code>"dataClasses"</code> attribute (if any) of the <code>"terms"</code> attribute of the model frame.                                                                                       |
| <code>model</code>                | if <code>model = TRUE</code> , the model frame.                                                                                                                                                   |
| <code>weights</code>              | if <code>weights</code> is supplied, the weights.                                                                                                                                                 |
| <code>convInfo</code>             | a list with convergence information.                                                                                                                                                              |
| <code>control</code>              | the control list used, see the control argument.                                                                                                                                                  |
| <code>convergence, message</code> | for an <code>algorithm = "port"</code> fit only, a convergence code (0 for convergence) and message.<br>To use these is <i>deprecated</i> , as they are available from <code>convInfo</code> now. |

### Warning

#### Do not use nls on artificial "zero-residual" data.

The `nls` function uses a relative-offset convergence criterion that compares the numerical imprecision at the current parameter estimates to the residual sum-of-squares. This performs well on data of the form

$$y = f(x, \theta) + \epsilon$$

(with  $\text{var}(\epsilon) > 0$ ). It fails to indicate convergence on data of the form

$$y = f(x, \theta)$$

because the criterion amounts to comparing two components of the round-off error. If you wish to test `nls` on artificial data please add a noise component, as shown in the example below.

The `algorithm = "port"` code appears unfinished, and does not even check that the starting value is within the bounds. Use with caution, especially where bounds are supplied.

### Note

Setting `warnOnly = TRUE` in the control argument (see `nls.control`) returns a non-converged object (since R version 2.5.0) which might be useful for further convergence analysis, *but not for inference*.

nls.control

*Control the Iterations in nls*

---

## Description

Allow the user to set some characteristics of the nls nonlinear least squares algorithm.

## Usage

```
nls.control(maxiter = 50, tol = 1e-05, minFactor = 1/1024,
            printEval = FALSE, warnOnly = FALSE)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| maxiter   | A positive integer specifying the maximum number of iterations allowed.                                                                                                                                                                                                                                                                                        |
| tol       | A positive numeric value specifying the tolerance level for the relative offset convergence criterion.                                                                                                                                                                                                                                                         |
| minFactor | A positive numeric value specifying the minimum step-size factor allowed on any step in the iteration. The increment is calculated with a Gauss-Newton algorithm and successively halved until the residual sum of squares has been decreased or until the step-size factor has been reduced below this limit.                                                 |
| printEval | a logical specifying whether the number of evaluations (steps in the gradient direction taken each iteration) is printed.                                                                                                                                                                                                                                      |
| warnOnly  | a logical specifying whether <code>nls()</code> should return instead of signalling an error in the case of termination before convergence. Termination before convergence happens upon completion of <code>maxiter</code> iterations, in the case of a singular gradient, and in the case that the step-size factor is reduced below <code>minFactor</code> . |

## Value

A list with exactly five components:

```
maxiter
tol
minFactor
printEval
warnOnly
```

with meanings as explained under ‘Arguments’.

```

---

NLSstAsymptotic

*Fit the Asymptotic Regression Model*

---

**Description**

Fits the asymptotic regression model, in the form  $b_0 + b_1(1 - \exp(-\exp(lrc) * x))$  to the `xy` data. This can be used as a building block in determining starting estimates for more complicated models.

**Usage**

```
NLSstAsymptotic(xy)
```

**Arguments**

`xy` a sorted `XyData` object

**Value**

A numeric value of length 3 with components labelled `b0`, `b1`, and `lrc`. `b0` is the estimated intercept on the y-axis, `b1` is the estimated difference between the asymptote and the y-intercept, and `lrc` is the estimated logarithm of the rate constant.

**Author(s)**

José Pinheiro and Douglas Bates

|---------------|------------------------------|
| NLSstClosestX | <i>Inverse Interpolation</i> |
|---------------|------------------------------|

---

Description

Use inverse linear interpolation to approximate the x value at which the function represented by xy is equal to yval.

Usage

```
NLSstClosestX(xy, yval)
```

Arguments

- xy                    a sortedXyData object
- yval                 a numeric value on the y scale

Value

A single numeric value on the x scale.

NLSstClosestX(DN.srt, 1.0)
```

---

|                  |                                              |
|------------------|----------------------------------------------|
| NLSstLfAsymptote | <i>Horizontal Asymptote on the Left Side</i> |
|------------------|----------------------------------------------|

---

**Description**

Provide an initial guess at the horizontal asymptote on the left side (i.e., small values of x) of the graph of y versus x from the xy object. Primarily used within initial functions for self-starting nonlinear regression models.

**Usage**

```
NLSstLfAsymptote(xy)
```

**Arguments**

xy                    a sortedXyData object

**Value**

A single numeric value estimating the horizontal asymptote for small x.

|------------------|-----------------------------------------------|
| NLSstRtAsymptote | <i>Horizontal Asymptote on the Right Side</i> |
|------------------|-----------------------------------------------|

---

**Description**

Provide an initial guess at the horizontal asymptote on the right side (i.e., large values of x) of the graph of y versus x from the xy object. Primarily used within initial functions for self-starting nonlinear regression models.

**Usage**

```
NLSstRtAsymptote(xy)
```

**Arguments**

xy                    a sortedXyData object

**Value**

A single numeric value estimating the horizontal asymptote for large x.

**Author(s)**

José Pinheiro and Douglas Bates

NLSstRtAsymptote( DN.srt )
```

---

nobs

*Extract the Number of Observations from a Fit.*

---

**Description**

Extract the number of ‘observations’ from a model fit. This is principally intended to be used in computing BIC (see [AIC](#)).

**Usage**

```
nobs(object, ...)
```

## Default S3 method:

```
nobs(object, use.fallback = FALSE, ...)
```

**Arguments**

object                A fitted model object.

use.fallback        logical: should fallback methods be used to try to guess the value?

...                   Further arguments to be passed to methods.

Details

This is a generic function, with an S4 generic in package **stats4**. There are methods in this package for objects of classes `"lm"`, `"glm"`, `"nls"` and `"logLik"`, as well as a default method (which throws an error, unless `use.fallback = TRUE` when it looks for weights and residuals components – use with care!).

The main usage is in determining the appropriate penalty for BIC, but `nobs` is also used by the stepwise fitting methods `step`, `add1` and `drop1` as a quick check that different fits have been fitted to the same set of data (and not, say, that further rows have been dropped because of NAs in the new predictors).

For `lm`, `glm` and `nls` fits, observations with zero weight are not included.

Value

A single number, normally an integer. Could be NA.

See Also

[AIC](#).

---

|        |                                |
|--------|--------------------------------|
| Normal | <i>The Normal Distribution</i> |
|--------|--------------------------------|

---

Description

Density, distribution function, quantile function and random generation for the normal distribution with mean equal to mean and standard deviation equal to sd.

Usage

```
dnorm(x, mean = 0, sd = 1, log = FALSE)
pnorm(q, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
qnorm(p, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
rnorm(n, mean = 0, sd = 1)
```

Arguments

|            |                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------|
| x, q       | vector of quantiles.                                                                                      |
| p          | vector of probabilities.                                                                                  |
| n          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| mean       | vector of means.                                                                                          |
| sd         | vector of standard deviations.                                                                            |
| log, log.p | logical; if TRUE, probabilities p are given as $\log(p)$ .                                                |
| lower.tail | logical; if TRUE (default), probabilities are $P[X \leq x]$ otherwise, $P[X > x]$ .                       |

### Details

If mean or sd are not specified they assume the default values of 0 and 1, respectively.

The normal distribution has density

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-(x-\mu)^2/2\sigma^2}$$

where  $\mu$  is the mean of the distribution and  $\sigma$  the standard deviation.

### Value

dnorm gives the density, pnorm gives the distribution function, qnorm gives the quantile function, and rnorm generates random deviates.

The length of the result is determined by n for rnorm, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

For sd = 0 this gives the limit as sd decreases to 0, a point mass at mu. sd < 0 is an error and returns NaN.

### Source

For pnorm, based on

Cody, W. D. (1993) Algorithm 715: SPECFUN – A portable FORTRAN package of special function routines and test drivers. *ACM Transactions on Mathematical Software* **19**, 22–32.

For qnorm, the code is a C translation of

Wichura, M. J. (1988) Algorithm AS 241: The percentage points of the normal distribution. *Applied Statistics*, **37**, 477–484.

which provides precise results up to about 16 digits.

For rnorm, see [RNG](#) for how to select the algorithm and for references to the supplied methods.

dnorm(1) == 1/sqrt(2*pi*exp(1))

## Using "log = TRUE" for an extended range :
par(mfrow = c(2,1))
plot(function(x) dnorm(x, log = TRUE), -60, 50,
     main = "log { Normal density }")
curve(log(dnorm(x)), add = TRUE, col = "red", lwd = 2)
mtext("dnorm(x, log=TRUE)", adj = 0)
mtext("log(dnorm(x))", col = "red", adj = 1)

plot(function(x) pnorm(x, log.p = TRUE), -50, 10,
     main = "log { Normal Cumulative }")
curve(log(pnorm(x)), add = TRUE, col = "red", lwd = 2)
mtext("pnorm(x, log=TRUE)", adj = 0)
mtext("log(pnorm(x))", col = "red", adj = 1)

## if you want the so-called 'error function'
erf <- function(x) 2 * pnorm(x * sqrt(2)) - 1
## (see Abramowitz and Stegun 29.2.29)
## and the so-called 'complementary error function'
erfc <- function(x) 2 * pnorm(x * sqrt(2), lower = FALSE)
## and the inverses
erfinv <- function (x) qnorm((1 + x)/2)/sqrt(2)
erfcinv <- function (x) qnorm(x/2, lower = FALSE)/sqrt(2)
```

---

numericDeriv

*Evaluate Derivatives Numerically*

---

## Description

numericDeriv numerically evaluates the gradient of an expression.

## Usage

```
numericDeriv(expr, theta, rho = parent.frame(), dir = 1.0)
```

## Arguments

|       |                                                                                               |
|-------|-----------------------------------------------------------------------------------------------|
| expr  | The expression to be differentiated. The value of this expression should be a numeric vector. |
| theta | A character vector of names of numeric variables used in expr.                                |
| rho   | An environment containing all the variables needed to evaluate expr.                          |
| dir   | A numeric vector of directions to use for the finite differences.                             |

**Details**

This is a front end to the C function `numeric_deriv`, which is described in *Writing R Extensions*.

The numeric variables must be of type real and not integer.

**Value**

The value of `eval(expr, envir = rho)` plus a matrix attribute called `gradient`. The columns of this matrix are the derivatives of the value with respect to the variables listed in `theta`.

**Author(s)**

Saikat DebRoy <saikat@stat.wisc.edu>

**Examples**

```
myenv <- new.env()
assign("mean", 0., envir = myenv)
assign("sd", 1., envir = myenv)
assign("x", seq(-3., 3., len = 31), envir = myenv)
numericDeriv(quote(pnorm(x, mean, sd)), c("mean", "sd"), myenv)
```

---

offset

---

*Include an Offset in a Model Formula*

---

**Description**

An offset is a term to be added to a linear predictor, such as in a generalised linear model, with known coefficient 1 rather than an estimated coefficient.

**Usage**

```
offset(object)
```

**Arguments**

`object`                      An offset to be included in a model frame

**Details**

There can be more than one offset in a model formula, but `-` is not supported for offset terms (and is equivalent to `+`).

**Value**

The input value.

**See Also**

[model.offset](#), [model.frame](#).

For examples see [glm](#) and [Insurance](#) in package **MASS**.

---

|             |                                                 |
|-------------|-------------------------------------------------|
| oneway.test | <i>Test for Equal Means in a One-Way Layout</i> |
|-------------|-------------------------------------------------|

---

**Description**

Test whether two or more samples from normal distributions have the same means. The variances are not necessarily assumed to be equal.

**Usage**

```
oneway.test(formula, data, subset, na.action, var.equal = FALSE)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the sample values and <code>rhs</code> the corresponding groups.                                                                                                                                                                                                                                           |
| data      | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .                                                                                                                                                           |
| subset    | an optional vector specifying a subset of observations to be used.                                                                                                                                                                                                                                                                                                                   |
| na.action | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                                                                                                                                                                           |
| var.equal | a logical variable indicating whether to treat the variances in the samples as equal. If <code>TRUE</code> , then a simple F test for the equality of means in a one-way analysis of variance is performed. If <code>FALSE</code> , an approximate method of Welch (1951) is used, which generalizes the commonly known 2-sample Welch test to the case of arbitrarily many samples. |

**Details**

If the right-hand side of the formula contains more than one term, their interaction is taken to form the grouping.

**Value**

A list with class "htest" containing the following components:

|           |                                                                                          |
|-----------|------------------------------------------------------------------------------------------|
| statistic | the value of the test statistic.                                                         |
| parameter | the degrees of freedom of the exact or approximate F distribution of the test statistic. |
| p.value   | the p-value of the test.                                                                 |
| method    | a character string indicating the test performed.                                        |
| data.name | a character string giving the names of the data.                                         |

## References

The standard t test ([t.test](#)) as the special case for two samples; the Kruskal-Wallis test [kruskal.test](#) for a nonparametric test for equal location parameters in a one-way layout.

## Examples

```
## Not assuming equal variances
oneway.test(extra ~ group, data = sleep)
## Assuming equal variances
oneway.test(extra ~ group, data = sleep, var.equal = TRUE)
## which gives the same result as
anova(lm(extra ~ group, data = sleep))
```

---

optim

*General-purpose Optimization*

---

## Description

General-purpose optimization based on Nelder–Mead, quasi-Newton and conjugate-gradient algorithms. It includes an option for box-constrained optimization and simulated annealing.

## Usage

```
optim(par, fn, gr = NULL, ...,
      method = c("Nelder-Mead", "BFGS", "CG", "L-BFGS-B", "SANN",
                  "Brent"),
      lower = -Inf, upper = Inf,
      control = list(), hessian = FALSE)

optimHess(par, fn, gr = NULL, ..., control = list())
```

## Arguments

|                  |                                                                                                                                                                                                                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>par</code> | Initial values for the parameters to be optimized over.                                                                                                                                                                                                                                   |
| <code>fn</code>  | A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.                                                                                                                       |
| <code>gr</code>  | A function to return the gradient for the "BFGS", "CG" and "L-BFGS-B" methods. If it is NULL, a finite-difference approximation will be used.<br>For the "SANN" method it specifies a function to generate a new candidate point. If it is NULL a default Gaussian Markov kernel is used. |

|                                         |                                                                                                            |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------|
| ...                                     | Further arguments to be passed to <code>fn</code> and <code>gr</code> .                                    |
| <code>method</code>                     | The method to be used. See ‘Details’. Can be abbreviated.                                                  |
| <code>lower</code> , <code>upper</code> | Bounds on the variables for the “L-BFGS-B” method, or bounds in which to <i>search</i> for method “Brent”. |
| <code>control</code>                    | A list of control parameters. See ‘Details’.                                                               |
| <code>hessian</code>                    | Logical. Should a numerically differentiated Hessian matrix be returned?                                   |

## Details

Note that arguments after ... must be matched exactly.

By default `optim` performs minimization, but it will maximize if `control$fnscale` is negative. `optimHess` is an auxiliary function to compute the Hessian at a later stage if `hessian = TRUE` was forgotten.

The default method is an implementation of that of Nelder and Mead (1965), that uses only function values and is robust but relatively slow. It will work reasonably well for non-differentiable functions.

Method “BFGS” is a quasi-Newton method (also known as a variable metric algorithm), specifically that published simultaneously in 1970 by Broyden, Fletcher, Goldfarb and Shanno. This uses function values and gradients to build up a picture of the surface to be optimized.

Method “CG” is a conjugate gradients method based on that by Fletcher and Reeves (1964) (but with the option of Polak–Ribiere or Beale–Sorenson updates). Conjugate gradient methods will generally be more fragile than the BFGS method, but as they do not store a matrix they may be successful in much larger optimization problems.

Method “L-BFGS-B” is that of Byrd *et al.* (1995) which allows *box constraints*, that is each variable can be given a lower and/or upper bound. The initial value must satisfy the constraints. This uses a limited-memory modification of the BFGS quasi-Newton method. If non-trivial bounds are supplied, this method will be selected, with a warning.

Nocedal and Wright (1999) is a comprehensive reference for the previous three methods.

Method “SANN” is by default a variant of simulated annealing given in Belisle (1992). Simulated-annealing belongs to the class of stochastic global optimization methods. It uses only function values but is relatively slow. It will also work for non-differentiable functions. This implementation uses the Metropolis function for the acceptance probability. By default the next candidate point is generated from a Gaussian Markov kernel with scale proportional to the actual temperature. If a function to generate a new candidate point is given, method “SANN” can also be used to solve combinatorial optimization problems. Temperatures are decreased according to the logarithmic cooling schedule as given in Belisle (1992, p. 890); specifically, the temperature is set to  $\text{temp} / \log(((t-1) \% \% \text{tmax}) * \text{tmax} + \exp(1)))$ , where  $t$  is the current iteration step and `temp` and `tmax` are specifiable via `control`, see below. Note that the “SANN” method depends critically on the settings of the control parameters. It is not a general-purpose method but can be very useful in getting to a good value on a very rough surface.

Method “Brent” is for one-dimensional problems only, using `optimize()`. It can be useful in cases where `optim()` is used inside other functions where only `method` can be specified, such as in `mle` from package **stats4**.

Function `fn` can return NA or Inf if the function cannot be evaluated at the supplied value, but the initial value must have a computable finite value of `fn`. (Except for method "L-BFGS-B" where the values should always be finite.)

`optim` can be used recursively, and for a single parameter as well as many. It also accepts a zero-length `par`, and just evaluates the function with that argument.

The control argument is a list that can supply any of the following components:

`trace` Non-negative integer. If positive, tracing information on the progress of the optimization is produced. Higher values may produce more tracing information: for method "L-BFGS-B" there are six levels of tracing. (To understand exactly what these do see the source code: higher levels give more detail.)

`fnscale` An overall scaling to be applied to the value of `fn` and `gr` during optimization. If negative, turns the problem into a maximization problem. Optimization is performed on `fn(par)/fnscale`.

`parscale` A vector of scaling values for the parameters. Optimization is performed on `par/parscale` and these should be comparable in the sense that a unit change in any element produces about a unit change in the scaled value. Not used (nor needed) for `method = "Brent"`.

`ndeps` A vector of step sizes for the finite-difference approximation to the gradient, on `par/parscale` scale. Defaults to  $1e-3$ .

`maxit` The maximum number of iterations. Defaults to 100 for the derivative-based methods, and 500 for "Nelder-Mead".

For "SANN" `maxit` gives the total number of function evaluations: there is no other stopping criterion. Defaults to 10000.

`abstol` The absolute convergence tolerance. Only useful for non-negative functions, as a tolerance for reaching zero.

`reltol` Relative convergence tolerance. The algorithm stops if it is unable to reduce the value by a factor of `reltol * (abs(val) + reltol)` at a step. Defaults to `sqrt(.Machine$double.eps)`, typically about  $1e-8$ .

`alpha`, `beta`, `gamma` Scaling parameters for the "Nelder-Mead" method. `alpha` is the reflection factor (default 1.0), `beta` the contraction factor (0.5) and `gamma` the expansion factor (2.0).

`REPORT` The frequency of reports for the "BFGS", "L-BFGS-B" and "SANN" methods if `control$trace` is positive. Defaults to every 10 iterations for "BFGS" and "L-BFGS-B", or every 100 temperatures for "SANN".

`type` for the conjugate-gradients method. Takes value 1 for the Fletcher-Reeves update, 2 for Polak-Ribiere and 3 for Beale-Sorenson.

`lmm` is an integer giving the number of BFGS updates retained in the "L-BFGS-B" method, It defaults to 5.

`factr` controls the convergence of the "L-BFGS-B" method. Convergence occurs when the reduction in the objective is within this factor of the machine tolerance. Default is  $1e7$ , that is a tolerance of about  $1e-8$ .

`pgtol` helps control the convergence of the "L-BFGS-B" method. It is a tolerance on the projected gradient in the current search direction. This defaults to zero, when the check is suppressed.

`temp` controls the "SANN" method. It is the starting temperature for the cooling schedule. Defaults to 10.

`tmax` is the number of function evaluations at each temperature for the "SANN" method. Defaults to 10.

Any names given to `par` will be copied to the vectors passed to `fn` and `gr`. Note that no other attributes of `par` are copied over.

The parameter vector passed to `fn` has special semantics and may be shared between calls: the function should not change or copy it.

## Value

For `optim`, a list with components:

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>par</code>         | The best set of parameters found.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>value</code>       | The value of <code>fn</code> corresponding to <code>par</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>counts</code>      | A two-element integer vector giving the number of calls to <code>fn</code> and <code>gr</code> respectively. This excludes those calls needed to compute the Hessian, if requested, and any calls to <code>fn</code> to compute a finite-difference approximation to the gradient.                                                                                                                                                                                                                                                   |
| <code>convergence</code> | An integer code. 0 indicates successful completion (which is always the case for "SANN" and "Brent"). Possible error codes are <ul style="list-style-type: none"> <li>1 indicates that the iteration limit <code>maxit</code> had been reached.</li> <li>10 indicates degeneracy of the Nelder–Mead simplex.</li> <li>51 indicates a warning from the "L-BFGS-B" method; see component message for further details.</li> <li>52 indicates an error from the "L-BFGS-B" method; see component message for further details.</li> </ul> |
| <code>message</code>     | A character string giving any additional information returned by the optimizer, or NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>hessian</code>     | Only if argument <code>hessian</code> is true. A symmetric matrix giving an estimate of the Hessian at the solution found. Note that this is the Hessian of the unconstrained problem even if the box constraints are active.                                                                                                                                                                                                                                                                                                        |

For `optimHess`, the description of the `hessian` component applies.

## Note

`optim` will work with one-dimensional `pars`, but the default method does not work well (and will warn). Method "Brent" uses [optimize](#) and needs bounds to be available; "BFGS" often works well enough if not.

## Source

The code for methods "Nelder–Mead", "BFGS" and "CG" was based originally on Pascal code in Nash (1990) that was translated by p2c and then hand-optimized. Dr Nash has agreed that the code can be made freely available.

The code for method "L-BFGS-B" is based on Fortran code by Zhu, Byrd, Lu-Chen and Nocedal obtained from Netlib (file `'opt/lbfgs_bcm.shar'`: another version is in `'toms/778'`).

The code for method "SANN" was contributed by A. Trapletti.

optimize

*One Dimensional Optimization***Description**

The function `optimize` searches the interval from `lower` to `upper` for a minimum or maximum of the function `f` with respect to its first argument.

`optimise` is an alias for `optimize`.

**Usage**

```

optimize(f = , interval = , ..., lower = min(interval),
         upper = max(interval), maximum = FALSE,
         tol = .Machine$double.eps^0.25)
optimise(f = , interval = , ..., lower = min(interval),
        upper = max(interval), maximum = FALSE,
        tol = .Machine$double.eps^0.25)

```

**Arguments**

|                       |                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>        | the function to be optimized. The function is either minimized or maximized over its first argument depending on the value of <code>maximum</code> . |
| <code>interval</code> | a vector containing the end-points of the interval to be searched for the minimum.                                                                   |
| <code>...</code>      | additional named or unnamed arguments to be passed to <code>f</code> .                                                                               |
| <code>lower</code>    | the lower end point of the interval to be searched.                                                                                                  |
| <code>upper</code>    | the upper end point of the interval to be searched.                                                                                                  |
| <code>maximum</code>  | logical. Should we maximize or minimize (the default)?                                                                                               |
| <code>tol</code>      | the desired accuracy.                                                                                                                                |

**Details**

Note that arguments after `...` must be matched exactly.

The method used is a combination of golden section search and successive parabolic interpolation, and was designed for use with continuous functions. Convergence is never much slower than that for a Fibonacci search. If `f` has a continuous second derivative which is positive at the minimum (which is not at `lower` or `upper`), then convergence is superlinear, and usually of the order of about 1.324.

The function `f` is never evaluated at two points closer together than  $\epsilon|x_0| + (tol/3)$ , where  $\epsilon$  is approximately `sqrt(.Machine$double.eps)` and  $x_0$  is the final abscissa `optimize()`\$minimum.

If  $f$  is a unimodal function and the computed values of  $f$  are always unimodal when separated by at least  $\epsilon |x| + (tol/3)$ , then  $x_0$  approximates the abscissa of the global minimum of  $f$  on the interval  $lower, upper$  with an error less than  $\epsilon |x_0| + tol$ .

If  $f$  is not unimodal, then `optimize()` may approximate a local, but perhaps non-global, minimum to the same accuracy.

The first evaluation of  $f$  is always at  $x_1 = a + (1 - \phi)(b - a)$  where  $(a, b) = (lower, upper)$  and  $\phi = (\sqrt{5} - 1)/2 = 0.61803..$  is the golden section ratio. Almost always, the second evaluation is at  $x_2 = a + \phi(b - a)$ . Note that a local minimum inside  $[x_1, x_2]$  will be found as solution, even when  $f$  is constant in there, see the last example.

$f$  will be called as  $f(x, \dots)$  for a numeric value of  $x$ .

The argument passed to  $f$  has special semantics and used to be shared between calls. The function should not copy it.

### Value

A list with components `minimum` (or `maximum`) and `objective` which give the location of the minimum (or maximum) and the value of the function at that point.

### Source

A C translation of Fortran code <http://www.netlib.org/fmm/fmin.f> (author(s) unstated) based on the Algol 60 procedure `localmin` given in the reference.

### References

Brent, R. (1973) *Algorithms for Minimization without Derivatives*. Englewood Cliffs N.J.: Prentice-Hall.

### Examples

```
require(graphics)

f <- function(x, a) (x - a)^2
xmin <- optimize(f, c(0, 1), tol = 0.0001, a = 1/3)
xmin

## See where the function is evaluated:
optimize(function(x) x^2*(print(x)-1), lower = 0, upper = 10)

## "wrong" solution with unlucky interval and piecewise constant f():
f <- function(x) ifelse(x > -1, ifelse(x < 4, exp(-1/abs(x - 1)), 10), 10)
fp <- function(x) { print(x); f(x) }

plot(f, -2,5, ylim = 0:1, col = 2)
optimize(fp, c(-4, 20)) # doesn't see the minimum
optimize(fp, c(-7, 20)) # ok
```

---

`order.dendrogram`*Ordering or Labels of the Leaves in a Dendrogram*

---

### Description

These functions return the order (index) or the "label" attribute for the leaves in a dendrogram. These indices can then be used to access the appropriate components of any additional data.

### Usage

```
order.dendrogram(x)

## S3 method for class 'dendrogram'
labels(object, ...)
```

### Arguments

|                        |                                                    |
|------------------------|----------------------------------------------------|
| <code>x, object</code> | a dendrogram (see <a href="#">as.dendrogram</a> ). |
| <code>...</code>       | additional arguments                               |

### Details

The indices or labels for the leaves in left to right order are retrieved.

### Value

A vector with length equal to the number of leaves in the dendrogram is returned. From `r <- order.dendrogram()`, each element is the index into the original data (from which the dendrogram was computed).

### Author(s)

R. Gentleman (`order.dendrogram`) and Martin Maechler (`labels.dendrogram`).

### See Also

[reorder](#), [dendrogram](#).

### Examples

```
set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
hc$order
dd <- as.dendrogram(hc)
order.dendrogram(dd) ## the same :
stopifnot(hc$order == order.dendrogram(dd))
```

```
d2 <- as.dendrogram(hclust(dist(USArrests)))
labels(d2) ## in this case the same as
stopifnot(identical(labels(d2),
  rownames(USArrests)[order.dendrogram(d2)]))
```

p.adjust

*Adjust P-values for Multiple Comparisons*

## Description

Given a set of p-values, returns p-values adjusted using one of several methods.

## Usage

```
p.adjust(p, method = p.adjust.methods, n = length(p))

p.adjust.methods
# c("holm", "hochberg", "hommel", "bonferroni", "BH", "BY",
#   "fdr", "none")
```

## Arguments

|        |                                                                                                                                   |
|--------|-----------------------------------------------------------------------------------------------------------------------------------|
| p      | numeric vector of p-values (possibly with <a href="#">NAs</a> ). Any other R is coerced by <a href="#">as.numeric</a> .           |
| method | correction method. Can be abbreviated.                                                                                            |
| n      | number of comparisons, must be at least <code>length(p)</code> ; only set this (to non-default) when you know what you are doing! |

## Details

The adjustment methods include the Bonferroni correction ("bonferroni") in which the p-values are multiplied by the number of comparisons. Less conservative corrections are also included by Holm (1979) ("holm"), Hochberg (1988) ("hochberg"), Hommel (1988) ("hommel"), Benjamini & Hochberg (1995) ("BH" or its alias "fdr"), and Benjamini & Yekutieli (2001) ("BY"), respectively. A pass-through option ("none") is also included. The set of methods are contained in the `p.adjust.methods` vector for the benefit of methods that need to have the method as an option and pass it on to `p.adjust`.

The first four methods are designed to give strong control of the family-wise error rate. There seems no reason to use the unmodified Bonferroni correction because it is dominated by Holm's method, which is also valid under arbitrary assumptions.

Hochberg's and Hommel's methods are valid when the hypothesis tests are independent or when they are non-negatively associated (Sarkar, 1998; Sarkar and Chang, 1997). Hommel's method is more powerful than Hochberg's, but the difference is usually small and the Hochberg p-values are faster to compute.

The "BH" (aka "fdr") and "BY" method of Benjamini, Hochberg, and Yekutieli control the false discovery rate, the expected proportion of false discoveries amongst the rejected hypotheses. The

false discovery rate is a less stringent condition than the family-wise error rate, so these methods are more powerful than the others.

Note that you can set `n` larger than `length(p)` which means the unobserved p-values are assumed to be greater than all the observed p for "bonferroni" and "holm" methods and equal to 1 for the other methods.

## Value

A numeric vector of corrected p-values (of the same length as `p`, with names copied from `p`).

               alternative = c("two.sided", "less", "greater"),
               ...)
```

**Arguments**

|                 |                                                                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------|
| x               | response vector.                                                                                                                         |
| g               | grouping vector or factor.                                                                                                               |
| p.adjust.method | Method for adjusting p values (see <a href="#">p.adjust</a> ).                                                                           |
| pool.sd         | switch to allow/disallow the use of a pooled SD                                                                                          |
| paired          | a logical indicating whether you want paired t-tests.                                                                                    |
| alternative     | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". Can be abbreviated. |
| ...             | additional arguments to pass to t.test.                                                                                                  |

**Details**

The pool.sd switch calculates a common SD for all groups and uses that for all comparisons (this can be useful if some groups are small). This method does not actually call t.test, so extra arguments are ignored. Pooling does not generalize to paired tests so pool.sd and paired cannot both be TRUE.

Only the lower triangle of the matrix of possible comparisons is being calculated, so setting alternative to anything other than "two.sided" requires that the levels of g are ordered sensibly.

**Value**

Object of class "pairwise.htest"

**See Also**

[t.test](#), [p.adjust](#)

**Examples**

```
attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
pairwise.t.test(Ozone, Month)
pairwise.t.test(Ozone, Month, p.adj = "bonf")
pairwise.t.test(Ozone, Month, pool.sd = FALSE)
detach()
```

---

|                |                                                   |
|----------------|---------------------------------------------------|
| pairwise.table | <i>Tabulate p values for pairwise comparisons</i> |
|----------------|---------------------------------------------------|

---

**Description**

Creates table of p values for pairwise comparisons with corrections for multiple testing.

**Usage**

```
pairwise.table(compare.levels, level.names, p.adjust.method)
```

**Arguments**

`compare.levels` Function to compute (raw) p value given indices i and j  
`level.names` Names of the group levels  
`p.adjust.method` Method for multiple testing adjustment. Can be abbreviated.

**Details**

Functions that do multiple group comparisons create separate `compare.levels` functions (assumed to be symmetrical in i and j) and passes them to this function.

**Value**

Table of p values in lower triangular form.

**See Also**

[pairwise.t.test](#)

---

pairwise.wilcox.test    *Pairwise Wilcoxon Rank Sum Tests*

---

## Description

Calculate pairwise comparisons between group levels with corrections for multiple testing.

## Usage

```
pairwise.wilcox.test(x, g, p.adjust.method = p.adjust.methods,  
                    paired = FALSE, ...)
```

## Arguments

|                 |                                                                                    |
|-----------------|------------------------------------------------------------------------------------|
| x               | response vector.                                                                   |
| g               | grouping vector or factor.                                                         |
| p.adjust.method | method for adjusting p values (see <a href="#">p.adjust</a> ). Can be abbreviated. |
| paired          | a logical indicating whether you want a paired test.                               |
| ...             | additional arguments to pass to <a href="#">wilcox.test</a> .                      |

## Details

Extra arguments that are passed on to `wilcox.test` may or may not be sensible in this context. In particular, only the lower triangle of the matrix of possible comparisons is being calculated, so setting alternative to anything other than "two.sided" requires that the levels of `g` are ordered sensibly.

## Value

Object of class "pairwise.htest"

## See Also

[wilcox.test](#), [p.adjust](#)

## Examples

```
attach(airquality)  
Month <- factor(Month, labels = month.abb[5:9])  
## These give warnings because of ties :  
pairwise.wilcox.test(Ozone, Month)  
pairwise.wilcox.test(Ozone, Month, p.adj = "bonf")  
detach()
```

**Description**

Plot method for objects of class "acf".

**Usage**

```
## S3 method for class 'acf'
plot(x, ci = 0.95, type = "h", xlab = "Lag", ylab = NULL,
     ylim = NULL, main = NULL,
     ci.col = "blue", ci.type = c("white", "ma"),
     max.mfrow = 6, ask = Npgs > 1 && dev.interactive(),
     mar = if(nser > 2) c(3,2,2,0.8) else par("mar"),
     oma = if(nser > 2) c(1,1.2,1,1) else par("oma"),
     mgp = if(nser > 2) c(1.5,0.6,0) else par("mgp"),
     xpd = par("xpd"),
     cex.main = if(nser > 2) 1 else par("cex.main"),
     verbose = getOption("verbose"),
     ...)
```

**Arguments**

|                                           |                                                                                                                                                                     |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                            | an object of class "acf".                                                                                                                                           |
| <code>ci</code>                           | coverage probability for confidence interval. Plotting of the confidence interval is suppressed if <code>ci</code> is zero or negative.                             |
| <code>type</code>                         | the type of plot to be drawn, default to histogram like vertical lines.                                                                                             |
| <code>xlab</code>                         | the x label of the plot.                                                                                                                                            |
| <code>ylab</code>                         | the y label of the plot.                                                                                                                                            |
| <code>ylim</code>                         | numeric of length 2 giving the y limits for the plot.                                                                                                               |
| <code>main</code>                         | overall title for the plot.                                                                                                                                         |
| <code>ci.col</code>                       | colour to plot the confidence interval lines.                                                                                                                       |
| <code>ci.type</code>                      | should the confidence limits assume a white noise input or for lag $k$ an $MA(k-1)$ input? Can be abbreviated.                                                      |
| <code>max.mfrow</code>                    | positive integer; for multivariate <code>x</code> indicating how many rows and columns of plots should be put on one page, using <code>par(mfrow = c(m,m))</code> . |
| <code>ask</code>                          | logical; if TRUE, the user is asked before a new page is started.                                                                                                   |
| <code>mar, oma, mgp, xpd, cex.main</code> | graphics parameters as in <code>par(*)</code> , by default adjusted to use smaller than default margins for multivariate <code>x</code> only.                       |
| <code>verbose</code>                      | logical. Should R report extra information on progress?                                                                                                             |
| <code>...</code>                          | graphics parameters to be passed to the plotting routines.                                                                                                          |

**Note**

The confidence interval plotted in `plot.acf` is based on an *uncorrelated* series and should be treated with appropriate caution. Using `ci.type = "ma"` may be less potentially misleading.

**See Also**

[acf](#) which calls `plot.acf` by default.

**Examples**

```
require(graphics)

z4 <- ts(matrix(rnorm(400), 100, 4), start = c(1961, 1), frequency = 12)
z7 <- ts(matrix(rnorm(700), 100, 7), start = c(1961, 1), frequency = 12)
acf(z4)
acf(z7, max.mfrow = 7) # squeeze onto 1 page
acf(z7) # multi-page
```

---

plot.density

---

*Plot Method for Kernel Density Estimation*

---

**Description**

The plot method for density objects.

**Usage**

```
## S3 method for class 'density'
plot(x, main = NULL, xlab = NULL, ylab = "Density", type = "l",
     zero.line = TRUE, ...)
```

**Arguments**

`x` a "density" object.  
`main`, `xlab`, `ylab`, `type` plotting parameters with useful defaults.  
`...` further plotting parameters.  
`zero.line` logical; if TRUE, add a base line at  $y = 0$

**Value**

None.

**See Also**

[density](#).

---

|------------------|----------------------------------------------|
| plot.HoltWinters | <i>Plot function for HoltWinters objects</i> |
|------------------|----------------------------------------------|

---

### Description

Produces a chart of the original time series along with the fitted values. Optionally, predicted values (and their confidence bounds) can also be plotted.

### Usage

```
## S3 method for class 'HoltWinters'
plot(x, predicted.values = NA, intervals = TRUE,
      separator = TRUE, col = 1, col.predicted = 2,
      col.intervals = 4, col.separator = 1, lty = 1,
      lty.predicted = 1, lty.intervals = 1, lty.separator = 3,
      ylab = "Observed / Fitted",
      main = "Holt-Winters filtering",
      ylim = NULL, ...)
```

### Arguments

|                              |                                                                                                                                                         |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| x                            | Object of class "HoltWinters"                                                                                                                           |
| predicted.values             | Predicted values as returned by predict.HoltWinters                                                                                                     |
| intervals                    | If TRUE, the prediction intervals are plotted (default).                                                                                                |
| separator                    | If TRUE, a separating line between fitted and predicted values is plotted (default).                                                                    |
| col, lty                     | Color/line type of original data (default: black solid).                                                                                                |
| col.predicted, lty.predicted | Color/line type of fitted and predicted values (default: red solid).                                                                                    |
| col.intervals, lty.intervals | Color/line type of prediction intervals (default: blue solid).                                                                                          |
| col.separator, lty.separator | Color/line type of observed/predicted values separator (default: black dashed).                                                                         |
| ylab                         | Label of the y-axis.                                                                                                                                    |
| main                         | Main title.                                                                                                                                             |
| ylim                         | Limits of the y-axis. If NULL, the range is chosen such that the plot contains the original series, the fitted values, and the predicted values if any. |
| ...                          | Other graphics parameters.                                                                                                                              |

## Description

The [plot](#) and [lines](#) method for R objects of class [isoreg](#).

## Usage

```
## S3 method for class 'isoreg'
plot(x, plot.type = c("single", "row.wise", "col.wise"),
     main = paste("Isotonic regression", deparse(x$call)),
     main2 = "Cumulative Data and Convex Minorant",
     xlab = "x0", ylab = "x$y",
     par.fit = list(col = "red", cex = 1.5, pch = 13, lwd = 1.5),
     mar = if (both) 0.1 + c(3.5, 2.5, 1, 1) else par("mar"),
     mgp = if (both) c(1.6, 0.7, 0) else par("mgp"),
     grid = length(x$x) < 12, ...)

## S3 method for class 'isoreg'
lines(x, col = "red", lwd = 1.5,
     do.points = FALSE, cex = 1.5, pch = 13, ...)
```

## Arguments

|                         |                                                                                                                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | an <a href="#">isoreg</a> object.                                                                                                                                                        |
| <code>plot.type</code>  | character indicating which type of plot is desired. The first (default) only draws the data and the fit, where the others add a plot of the cumulative data and fit. Can be abbreviated. |
| <code>main</code>       | main title of plot, see <a href="#">title</a> .                                                                                                                                          |
| <code>main2</code>      | title for second (cumulative) plot.                                                                                                                                                      |
| <code>xlab, ylab</code> | x- and y- axis annotation.                                                                                                                                                               |
| <code>par.fit</code>    | a <a href="#">list</a> of arguments (for <a href="#">points</a> and <a href="#">lines</a> ) for drawing the fit.                                                                         |
| <code>mar, mgp</code>   | graphical parameters, see <a href="#">par</a> , mainly for the case of two plots.                                                                                                        |

|                    |                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| grid               | logical indicating if grid lines should be drawn. If true, <code>grid()</code> is used for the first plot, where as vertical lines are drawn at ‘touching’ points for the cumulative plot. |
| do.points          | for <code>lines()</code> : logical indicating if the step points should be drawn as well (and as they are drawn in <code>plot()</code> ).                                                  |
| col, lwd, cex, pch | graphical arguments for <code>lines()</code> , where cex and pch are only used when do.points is TRUE.                                                                                     |
| ...                | further arguments passed to and from methods.                                                                                                                                              |

### Examples

```
require(graphics)

utils::example(isoreg) # for the examples there

plot(y3, main = "simple plot(.) + lines(<isoreg>")
lines(ir3)

## 'same' plot as above, "proving" that only ranks of 'x' are important
plot(isoreg(2^(1:9), c(1,0,4,3,3,5,4,2,0)), plot.type = "row", log = "x")

plot(ir3, plot.type = "row", ylab = "y3")
plot(isoreg(y3 - 4), plot.t="r", ylab = "y3 - 4")
plot(ir4, plot.type = "ro", ylab = "y4", xlab = "x = 1:n")

## experiment a bit with these (C-c C-j):
plot(isoreg(sample(9), y3), plot.type = "row")
plot(isoreg(sample(9), y3), plot.type = "col.wise")

plot(ir <- isoreg(sample(10), sample(10, replace = TRUE)),
      plot.type = "r")
```

### Description

Six plots (selectable by which) are currently available: a plot of residuals against fitted values, a Scale-Location plot of  $\sqrt{|residuals|}$  against fitted values, a Normal Q-Q plot, a plot of Cook’s distances versus row labels, a plot of residuals against leverages, and a plot of Cook’s distances against leverage/(1-leverage). By default, the first three and 5 are provided.

**Usage**

```
## S3 method for class 'lm'
plot(x, which = c(1:3, 5),
     caption = list("Residuals vs Fitted", "Normal Q-Q",
                    "Scale-Location", "Cook's distance",
                    "Residuals vs Leverage",
                    expression("Cook's dist vs Leverage " * h[ii] / (1 - h[ii]))),
     panel = if(add.smooth) panel.smooth else points,
     sub.caption = NULL, main = "",
     ask = prod(par("mfcol")) < length(which) && dev.interactive(),
     ...,
     id.n = 3, labels.id = names(residuals(x)), cex.id = 0.75,
     qqline = TRUE, cook.levels = c(0.5, 1.0),
     add.smooth = getOption("add.smooth"), label.pos = c(4,2),
     cex.caption = 1, cex.oma.main = 1.25)
```

**Arguments**

|                           |                                                                                                                                                                                                                                                                                          |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>            | lm object, typically result of <code>lm</code> or <code>glm</code> .                                                                                                                                                                                                                     |
| <code>which</code>        | if a subset of the plots is required, specify a subset of the numbers 1:6.                                                                                                                                                                                                               |
| <code>caption</code>      | captions to appear above the plots; <a href="#">character</a> vector or <a href="#">list</a> of valid graphics annotations, see <a href="#">as.graphicsAnnot</a> , of length 6, the j-th entry corresponding to <code>which[j]</code> . Can be set to "" or NA to suppress all captions. |
| <code>panel</code>        | panel function. The useful alternative to <a href="#">points</a> , <a href="#">panel.smooth</a> can be chosen by <code>add.smooth = TRUE</code> .                                                                                                                                        |
| <code>sub.caption</code>  | common title—above the figures if there are more than one; used as <code>sub</code> ( <a href="#">s.title</a> ) otherwise. If NULL, as by default, a possible abbreviated version of <code>deparse(x\$call)</code> is used.                                                              |
| <code>main</code>         | title to each plot—in addition to caption.                                                                                                                                                                                                                                               |
| <code>ask</code>          | logical; if TRUE, the user is <i>asked</i> before each plot, see <a href="#">par</a> ( <code>ask=.</code> ).                                                                                                                                                                             |
| <code>...</code>          | other parameters to be passed through to plotting functions.                                                                                                                                                                                                                             |
| <code>id.n</code>         | number of points to be labelled in each plot, starting with the most extreme.                                                                                                                                                                                                            |
| <code>labels.id</code>    | vector of labels, from which the labels for extreme points will be chosen. NULL uses observation numbers.                                                                                                                                                                                |
| <code>cex.id</code>       | magnification of point labels.                                                                                                                                                                                                                                                           |
| <code>qqline</code>       | logical indicating if a <a href="#">qqline</a> () should be added to the normal Q-Q plot.                                                                                                                                                                                                |
| <code>cook.levels</code>  | levels of Cook's distance at which to draw contours.                                                                                                                                                                                                                                     |
| <code>add.smooth</code>   | logical indicating if a smoother should be added to most plots; see also <code>panel</code> above.                                                                                                                                                                                       |
| <code>label.pos</code>    | positioning of labels, for the left half and right half of the graph respectively, for plots 1-3.                                                                                                                                                                                        |
| <code>cex.caption</code>  | controls the size of caption.                                                                                                                                                                                                                                                            |
| <code>cex.oma.main</code> | controls the size of the <code>sub.caption</code> only if that is <i>above</i> the figures when there is more than one.                                                                                                                                                                  |

## Details

sub.caption—by default the function call—is shown as a subtitle (under the x-axis title) on each plot when plots are on separate pages, or as a subtitle in the outer margin (if any) when there are multiple plots per page.

The ‘Scale-Location’ plot, also called ‘Spread-Location’ or ‘S-L’ plot, takes the square root of the absolute residuals in order to diminish skewness ( $\sqrt{|E|}$ ) is much less skewed than  $|E|$  for Gaussian zero-mean  $E$ ).

The ‘S-L’, the Q-Q, and the Residual-Leverage plot, use *standardized* residuals which have identical variance (under the hypothesis). They are given as  $R_i / (s \times \sqrt{1 - h_{ii}})$  where  $h_{ii}$  are the diagonal entries of the hat matrix, `influence()`\$hat (see also `hat`), and where the Residual-Leverage plot uses standardized Pearson residuals (`residuals.glm(type = "pearson")`) for  $R[i]$ .

The Residual-Leverage plot shows contours of equal Cook’s distance, for values of `cook.levels` (by default 0.5 and 1) and omits cases with leverage one with a warning. If the leverages are constant (as is typically the case in a balanced `av` situation) the plot uses factor level combinations instead of the leverages for the x-axis. (The factor levels are ordered by mean fitted value.)

In the Cook’s distance vs leverage/(1-leverage) plot, contours of standardized residuals that are equal in magnitude are lines through the origin. The contour lines are labelled with the magnitudes.

*Plot Ridge Functions for Projection Pursuit Regression Fit*

---

## Description

Plot ridge functions for projection pursuit regression fit.

## Usage

```
## S3 method for class 'ppr'
plot(x, ask, type = "o", ...)
```

## Arguments

|      |                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------|
| x    | A fit of class "ppr" as produced by a call to ppr.                                                               |
| ask  | the graphics parameter ask: see par for details. If set to TRUE will ask between the plot of each cross-section. |
| type | the type of line to draw                                                                                         |
| ...  | further graphical parameters                                                                                     |

## Value

None

## Side Effects

A series of plots are drawn on the current graphical device, one for each term in the fit.

```
require(graphics)

with(rock, {
  area1 <- area/10000; peri1 <- peri/10000
  par(mfrow = c(3,2)) # maybe: , pty = "s")
  rock.ppr <- ppr(log(perm) ~ area1 + peri1 + shape,
    data = rock, nterms = 2, max.terms = 5)
  plot(rock.ppr, main = "ppr(log(perm)~ ., nterms=2, max.terms=5)")
  plot(update(rock.ppr, bass = 5), main = "update(..., bass = 5)")
  plot(update(rock.ppr, sm.method = "gcv", gcvpen = 2),
    main = "update(..., sm.method=\"gcv\", gcvpen=2)")
})
```

plot.profile.nls

*Plot a profile.nls Object***Description**

Displays a series of plots of the profile t function and interpolated confidence intervals for the parameters in a nonlinear regression model that has been fit with `nls` and profiled with `profile.nls`.

**Usage**

```
## S3 method for class 'profile.nls'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100,
     absVal = TRUE, ylab = NULL, lty = 2, ...)
```

**Arguments**

|                        |                                                                                                                                                                        |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | an object of class "profile.nls"                                                                                                                                       |
| <code>levels</code>    | levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually <code>conf</code> is used instead of giving levels explicitly. |
| <code>conf</code>      | a numeric vector of confidence levels for profile-based confidence intervals on the parameters. Defaults to <code>c(0.99, 0.95, 0.90, 0.80, 0.50)</code> .             |
| <code>absVal</code>    | a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to <code>TRUE</code> .                     |
| <code>lty</code>       | the line type to be used for axis and dropped lines.                                                                                                                   |
| <code>ylab, ...</code> | other arguments to the <a href="#">plot.default</a> function can be passed here (but not <code>xlab</code> , <code>xlim</code> , <code>ylim</code> nor type).          |

## Details

The plots are produced in a set of hard-coded colours, but as these are coded by number their effect can be changed by setting the [palette](#). Colour 1 is used for the axes and 4 for the profile itself. Colours 3 and 6 are used for the axis line at zero and the horizontal/vertical lines dropping to the axes.

## Examples

```
require(graphics)

# obtain the fitted object
fm1 <- nls(demand ~ SSasymOrig(Time, A, lrc), data = BOD)
# get the profile for the fitted model
pr1 <- profile(fm1, alpha = 0.05)
opar <- par(mfrow = c(2,2), oma = c(1.1, 0, 1.1, 0), las = 1)
plot(pr1, conf = c(95, 90, 80, 50)/100)
plot(pr1, conf = c(95, 90, 80, 50)/100, absVal = FALSE)
mtext("Confidence intervals based on the profile sum of squares",
      side = 3, outer = TRUE)
mtext("BOD data - confidence levels of 50%, 80%, 90% and 95%",
      side = 1, outer = TRUE)
par(opar)
```

## Description

Plotting method for objects of class "spec". For multivariate time series it plots the marginal spectra of the series or pairs plots of the coherency and phase of the cross-spectra.

**Usage**

```
## S3 method for class 'spec'
plot(x, add = FALSE, ci = 0.95, log = c("yes", "dB", "no"),
     xlab = "frequency", ylab = NULL, type = "l",
     ci.col = "blue", ci.lty = 3,
     main = NULL, sub = NULL,
     plot.type = c("marginal", "coherency", "phase"),
     ...)

plot.spec.phase(x, ci = 0.95,
               xlab = "frequency", ylab = "phase",
               ylim = c(-pi, pi), type = "l",
               main = NULL, ci.col = "blue", ci.lty = 3, ...)

plot.spec.coherency(x, ci = 0.95,
                   xlab = "frequency",
                   ylab = "squared coherency",
                   ylim = c(0, 1), type = "l",
                   main = NULL, ci.col = "blue", ci.lty = 3, ...)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | an object of class "spec".                                                                                                                                                                                                                                                |
| add       | logical. If TRUE, add to already existing plot. Only valid for plot.type = "marginal".                                                                                                                                                                                    |
| ci        | coverage probability for confidence interval. Plotting of the confidence bar/limits is omitted unless ci is strictly positive.                                                                                                                                            |
| log       | If "dB", plot on log10 (decibel) scale (as S-PLUS), otherwise use conventional log scale or linear scale. Logical values are also accepted. The default is "yes" unless options(ts.S.compat = TRUE) has been set, when it is "dB". Only valid for plot.type = "marginal". |
| xlab      | the x label of the plot.                                                                                                                                                                                                                                                  |
| ylab      | the y label of the plot. If missing a suitable label will be constructed.                                                                                                                                                                                                 |
| type      | the type of plot to be drawn, defaults to lines.                                                                                                                                                                                                                          |
| ci.col    | colour for plotting confidence bar or confidence intervals for coherency and phase.                                                                                                                                                                                       |
| ci.lty    | line type for confidence intervals for coherency and phase.                                                                                                                                                                                                               |
| main      | overall title for the plot. If missing, a suitable title is constructed.                                                                                                                                                                                                  |
| sub       | a sub title for the plot. Only used for plot.type = "marginal". If missing, a description of the smoothing is used.                                                                                                                                                       |
| plot.type | For multivariate time series, the type of plot required. Only the first character is needed.                                                                                                                                                                              |
| ylim, ... | Graphical parameters.                                                                                                                                                                                                                                                     |

plot.stepfun

*Plot Step Functions***Description**

Method of the generic [plot](#) for [stepfun](#) objects and utility for plotting piecewise constant functions.

**Usage**

```
## S3 method for class 'stepfun'
plot(x, xval, xlim, ylim = range(c(y, Fn.kn)),
      xlab = "x", ylab = "f(x)", main = NULL,
      add = FALSE, verticals = TRUE, do.points = (n < 1000),
      pch = par("pch"), col = par("col"),
      col.points = col, cex.points = par("cex"),
      col.hor = col, col.vert = col,
      lty = par("lty"), lwd = par("lwd"), ...)
```

```
## S3 method for class 'stepfun'
lines(x, ...)
```

**Arguments**

|                         |                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | an R object inheriting from "stepfun".                                                                               |
| <code>xval</code>       | numeric vector of abscissa values at which to evaluate x. Defaults to <a href="#">knots</a> (x) restricted to xlim.  |
| <code>xlim, ylim</code> | limits for the plot region: see <a href="#">plot.window</a> . Both have sensible defaults if omitted.                |
| <code>xlab, ylab</code> | labels for x and y axis.                                                                                             |
| <code>main</code>       | main title.                                                                                                          |
| <code>add</code>        | logical; if TRUE only <i>add</i> to an existing plot.                                                                |
| <code>verticals</code>  | logical; if TRUE, draw vertical lines at steps.                                                                      |
| <code>do.points</code>  | logical; if TRUE, also draw points at the (xlim restricted) knot locations. Default is true, for sample size < 1000. |
| <code>pch</code>        | character; point character if do.points.                                                                             |
| <code>col</code>        | default color of all points and lines.                                                                               |
| <code>col.points</code> | character or integer code; color of points if do.points.                                                             |
| <code>cex.points</code> | numeric; character expansion factor if do.points.                                                                    |
| <code>col.hor</code>    | color of horizontal lines.                                                                                           |

|          |                                                                                   |
|----------|-----------------------------------------------------------------------------------|
| col.vert | color of vertical lines.                                                          |
| lty, lwd | line type and thickness for all lines.                                            |
| ...      | further arguments of <code>plot(.)</code> , or if(add) <code>segments(.)</code> . |

**Value**

A list with two components

|   |                                                        |
|---|--------------------------------------------------------|
| t | abscissa (x) values, including the two outermost ones. |
| y | y values 'in between' the t[.].                        |

  lines(list(sfun0, sfun.2, stepfun(1:3, y0, f = 1))[[i]], col = i)
legend(2.5, 1.9, paste("f =", c(0, 0.2, 1)), col = 1:3, lty = 1, y.intersp = 1)
par(op)

# Extend and/or restrict 'viewport':
plot(sfun0, xlim = c(0,5), ylim = c(0, 3.5),
     main = "plot(stepfun(*), xlim= . , ylim = .)")

##-- this works too (automatic call to ecdf(.)):
plot.stepfun(rt(50, df = 3), col.vert = "gray20")
```

plot.ts

Plotting Time-Series Objects

**Description**

Plotting method for objects inheriting from class "ts".

**Usage**

```
## S3 method for class 'ts'
plot(x, y = NULL, plot.type = c("multiple", "single"),
      xy.labels, xy.lines, panel = lines, nc, yax.flip = FALSE,
      mar.multi = c(0, 5.1, 0, if(yax.flip) 5.1 else 2.1),
      oma.multi = c(6, 0, 5, 0), axes = TRUE, ...)

## S3 method for class 'ts'
lines(x, ...)
```

**Arguments**

|                      |                                                                                                                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x, y                 | time series objects, usually inheriting from class "ts".                                                                                                                                                        |
| plot.type            | for multivariate time series, should the series be plotted separately (with a common time axis) or on a single plot? Can be abbreviated.                                                                        |
| xy.labels            | logical, indicating if <code>text()</code> labels should be used for an x-y plot, <i>or</i> character, supplying a vector of labels to be used. The default is to label for up to 150 points, and not for more. |
| xy.lines             | logical, indicating if <code>lines</code> should be drawn for an x-y plot. Defaults to the value of <code>xy.labels</code> if that is logical, otherwise to TRUE.                                               |
| panel                | a function(x, col, bg, pch, type, ...) which gives the action to be carried out in each panel of the display for <code>plot.type = "multiple"</code> . The default is <code>lines</code> .                      |
| nc                   | the number of columns to use when <code>type = "multiple"</code> . Defaults to 1 for up to 4 series, otherwise to 2.                                                                                            |
| yax.flip             | logical indicating if the y-axis (ticks and numbering) should flip from side 2 (left) to 4 (right) from series to series when <code>type = "multiple"</code> .                                                  |
| mar.multi, oma.multi | the (default) <code>par</code> settings for <code>plot.type = "multiple"</code> . Modify with care!                                                                                                             |
| axes                 | logical indicating if x- and y- axes should be drawn.                                                                                                                                                           |
| ...                  | additional graphical arguments, see <code>plot</code> , <code>plot.default</code> and <code>par</code> .                                                                                                        |

**Details**

If y is missing, this function creates a time series plot, for multivariate series of one of two kinds depending on `plot.type`.

If y is present, both x and y must be univariate, and a scatter plot  $y \sim x$  will be drawn, enhanced by using `text` if `xy.labels` is TRUE or character, and `lines` if `xy.lines` is TRUE.

**See Also**

[ts](#) for basic time series construction and access functionality.

**Examples**

```
require(graphics)

## Multivariate
z <- ts(matrix(rt(200 * 8, df = 3), 200, 8),
          start = c(1961, 1), frequency = 12)
plot(z, yax.flip = TRUE)
plot(z, axes = FALSE, ann = FALSE, frame.plot = TRUE,
      mar.multi = c(0,0,0,0), oma.multi = c(1,1,5,1))
title("plot(ts(..), axes=FALSE, ann=FALSE, frame.plot=TRUE, mar..., oma...)")

z <- window(z[,1:3], end = c(1969,12))
plot(z, type = "b")      # multiple
plot(z, plot.type = "single", lty = 1:3, col = 4:2)

## A phase plot:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
     main = "Lag plot of New Haven temperatures")

## xy.lines and xy.labels are FALSE for large series:
plot(lag(sunspots, 1), sunspots, pch = ".")

SMI <- EuStockMarkets[, "SMI"]
plot(lag(SMI, 1), SMI, pch = ".")
plot(lag(SMI, 20), SMI, pch = ".", log = "xy",
     main = "4 weeks lagged SMI stocks -- log scale", xy.lines = TRUE)
```

**Description**

Density, distribution function, quantile function and random generation for the Poisson distribution with parameter `lambda`.

**Usage**

```
dpois(x, lambda, log = FALSE)
ppois(q, lambda, lower.tail = TRUE, log.p = FALSE)
qpois(p, lambda, lower.tail = TRUE, log.p = FALSE)
rpois(n, lambda)
```

**Arguments**

|                         |                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------|
| <code>x</code>          | vector of (non-negative integer) quantiles.                                           |
| <code>q</code>          | vector of quantiles.                                                                  |
| <code>p</code>          | vector of probabilities.                                                              |
| <code>n</code>          | number of random values to return.                                                    |
| <code>lambda</code>     | vector of (non-negative) means.                                                       |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$ .               |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ . |

**Details**

The Poisson distribution has density

$$p(x) = \frac{\lambda^x e^{-\lambda}}{x!}$$

for  $x = 0, 1, 2, \dots$ . The mean and variance are  $E(X) = Var(X) = \lambda$ .

If an element of `x` is not integer, the result of `dpois` is zero, with a warning.  $p(x)$  is computed using Loader's algorithm, see the reference in [dbinom](#).

The quantile is right continuous: `qpois(p, lambda)` is the smallest integer  $x$  such that  $P(X \leq x) \geq p$ .

Setting `lower.tail = FALSE` allows to get much more precise results when the default, `lower.tail = TRUE` would return 1, see the example below.

**Value**

`dpois` gives the (log) density, `ppois` gives the (log) distribution function, `qpois` gives the quantile function, and `rpois` generates random deviates.

Invalid `lambda` will result in return value NaN, with a warning.

The length of the result is determined by `n` for `rpois`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Source**

`dpois` uses C code contributed by Catherine Loader (see [dbinom](#)).

`ppois` uses `pgamma`.

`qpois` uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

`rpois` uses

Ahrens, J. H. and Dieter, U. (1982). Computer generation of Poisson deviates from modified normal distributions. *ACM Transactions on Mathematical Software*, **8**, 163–179.

**See Also**

[Distributions](#) for other standard distributions, including [dbinom](#) for the binomial and [dnbinom](#) for the negative binomial distribution.

[poisson.test](#).

**Examples**

```
require(graphics)

-log(dpois(0:7, lambda = 1) * gamma(1+ 0:7)) # == 1
Ni <- rpois(50, lambda = 4); table(factor(Ni, 0:max(Ni)))

1 - ppois(10*(15:25), lambda = 100) # becomes 0 (cancellation)
  ppois(10*(15:25), lambda = 100, lower.tail = FALSE) # no cancellation

par(mfrow = c(2, 1))
x <- seq(-0.01, 5, 0.01)
plot(x, ppois(x, 1), type = "s", ylab = "F(x)", main = "Poisson(1) CDF")
plot(x, pbinom(x, 100, 0.01), type = "s", ylab = "F(x)",
      main = "Binomial(100, 0.01) CDF")
```

---

poisson.test

*Exact Poisson tests*

---

**Description**

Performs an exact test of a simple null hypothesis about the rate parameter in Poisson distribution, or for the ratio between two rate parameters.

**Usage**

```
poisson.test(x, T = 1, r = 1,
             alternative = c("two.sided", "less", "greater"),
             conf.level = 0.95)
```

**Arguments**

|             |                                                                                                                                    |
|-------------|------------------------------------------------------------------------------------------------------------------------------------|
| x           | number of events. A vector of length one or two.                                                                                   |
| T           | time base for event count. A vector of length one or two.                                                                          |
| r           | hypothesized rate or rate ratio                                                                                                    |
| alternative | indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. |
| conf.level  | confidence level for the returned confidence interval.                                                                             |

**Details**

Confidence intervals are computed similarly to those of [binom.test](#) in the one-sample case, and using [binom.test](#) in the two sample case.

**Value**

A list with class "htest" containing the following components:

|             |                                                                                            |
|-------------|--------------------------------------------------------------------------------------------|
| statistic   | the number of events (in the first sample if there are two.)                               |
| parameter   | the corresponding expected count                                                           |
| p.value     | the p-value of the test.                                                                   |
| conf.int    | a confidence interval for the rate or rate ratio.                                          |
| estimate    | the estimated rate or rate ratio.                                                          |
| null.value  | the rate or rate ratio under the null, r.                                                  |
| alternative | a character string describing the alternative hypothesis.                                  |
| method      | the character string "Exact Poisson test" or "Comparison of Poisson rates" as appropriate. |
| data.name   | a character string giving the names of the data.                                           |

**Note**

The rate parameter in Poisson data is often given based on a “time on test” or similar quantity (person-years, population size, or expected number of cases from mortality tables). This is the role of the T argument.

The one-sample case is effectively the binomial test with a very large n. The two sample case is converted to a binomial test by conditioning on the total event count, and the rate ratio is directly related to the odds in that binomial distribution.

**See Also**

[binom.test](#)

**Examples**

```
### These are paraphrased from data sets in the ISwR package

## SMR, Welsh Nickel workers
poisson.test(137, 24.19893)

## eba1977, compare Fredericia to other three cities for ages 55-59
poisson.test(c(11, 6+8+7), c(800, 1083+1050+878))
```

|      |                                       |
|------|---------------------------------------|
| poly | <i>Compute Orthogonal Polynomials</i> |
|------|---------------------------------------|

---

**Description**

Returns or evaluates orthogonal polynomials of degree 1 to degree over the specified set of points x: these are all orthogonal to the constant polynomial of degree 0. Alternatively, evaluate raw polynomials.

**Usage**

```
poly(x, ..., degree = 1, coefs = NULL, raw = FALSE, simple = FALSE)
polym (..., degree = 1, coefs = NULL, raw = FALSE)

## S3 method for class 'poly'
predict(object, newdata, ...)
```

**Arguments**

|                                       |                                                                                                                                                  |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> , <code>newdata</code> | a numeric vector at which to evaluate the polynomial. <code>x</code> can also be a matrix. Missing values are not allowed in <code>x</code> .    |
| <code>degree</code>                   | the degree of the polynomial. Must be less than the number of unique points if <code>raw = TRUE</code> .                                         |
| <code>coefs</code>                    | for prediction, coefficients from a previous fit.                                                                                                |
| <code>raw</code>                      | if true, use raw and not orthogonal polynomials.                                                                                                 |
| <code>simple</code>                   | logical indicating if a simple matrix (with no further <code>attributes</code> but <code>dimnames</code> ) should be returned. For speedup only. |
| <code>object</code>                   | an object inheriting from class "poly", normally the result of a call to <code>poly</code> with a single vector argument.                        |
| <code>...</code>                      | <code>poly</code> , <code>polym</code> : further vectors.<br><code>predict.poly</code> : arguments to be passed to or from other methods.        |

**Details**

Although formally `degree` should be named (as it follows `...`), an unnamed second argument of length 1 will be interpreted as the degree, such that `poly(x, 3)` can be used in formulas.

The orthogonal polynomial is summarized by the coefficients, which can be used to evaluate it via the three-term recursion given in Kennedy & Gentle (1980, pp. 343–4), and used in the `predict` part of the code.

`poly` using `...` is just a convenience wrapper for `polym`: `coef` is ignored. Conversely, if `polym` is called with a single argument in `...` it is a wrapper for `poly`.

**Value**

For `poly` and `polym()` (when `simple=FALSE` and `coefs=NULL` as per default):

A matrix with rows corresponding to points in `x` and columns corresponding to the degree, with attributes "degree" specifying the degrees of the columns and (unless `raw = TRUE`) "coefs" which contains the centering and normalization constants used in constructing the orthogonal polynomials and class `c("poly", "matrix")`.

For `poly(*, simple=TRUE)`, `polym(*, coefs=<non-NULL>)`, and `predict.poly()`: a matrix.

**Note**

This routine is intended for statistical purposes such as `contr.poly`: it does not attempt to orthogonalize to machine accuracy.

**Author(s)**

R Core Team. Keith Jewell (Camden BRI Group, UK) contributed improvements for correct prediction on subsets.

**Examples**

```
od <- options(digits = 3) # avoid too much visual clutter
(z <- poly(1:10, 3))
predict(z, seq(2, 4, 0.5))
zapsmall(poly(seq(4, 6, 0.5), 3, coefs = attr(z, "coefs")))

zm <- zapsmall(polym ( 1:4, c(1, 4:6), degree = 3)) # or just poly():
(z1 <- zapsmall(poly(cbind(1:4, c(1, 4:6)), degree = 3)))
## they are the same :
stopifnot(all.equal(zm, z1, tol = 1e-15))
options(od)
```

---

power

*Create a Power Link Object*

---

**Description**

Creates a link object based on the link function  $\eta = \mu^\lambda$ .

**Usage**

```
power(lambda = 1)
```

**Arguments**

lambda                      a real number.

**Details**

If lambda is non-positive, it is taken as zero, and the log link is obtained. The default lambda = 1 gives the identity link.

**Value**

A list with components `linkfun`, `linkinv`, `mu.eta`, and `valideta`. See [make.link](#) for information on their meaning.

**References**

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

**See Also**

[make.link](#), [family](#)

To raise a number to a power, see [Arithmetic](#).

To calculate the power of a test, see various functions in the **stats** package, e.g., [power.t.test](#).

**Examples**

```
power()
quasi(link = power(1/3))[c("linkfun", "linkinv")]
```

---

|                  |                                                                           |
|------------------|---------------------------------------------------------------------------|
| power.anova.test | <i>Power Calculations for Balanced One-Way Analysis of Variance Tests</i> |
|------------------|---------------------------------------------------------------------------|

---

**Description**

Compute power of test or determine parameters to obtain target power.

**Usage**

```
power.anova.test(groups = NULL, n = NULL,
                 between.var = NULL, within.var = NULL,
                 sig.level = 0.05, power = NULL)
```

**Arguments**

|                          |                                                   |
|--------------------------|---------------------------------------------------|
| <code>groups</code>      | Number of groups                                  |
| <code>n</code>           | Number of observations (per group)                |
| <code>between.var</code> | Between group variance                            |
| <code>within.var</code>  | Within group variance                             |
| <code>sig.level</code>   | Significance level (Type I error probability)     |
| <code>power</code>       | Power of test (1 minus Type II error probability) |

**Details**

Exactly one of the parameters `groups`, `n`, `between.var`, `power`, `within.var`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that `sig.level` has non-`NULL` default so `NULL` must be explicitly passed if you want it computed.

**Value**

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

**Note**

uniroot is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

**Author(s)**

Claus Ekstrøm

**See Also**

**Examples**

```
power.anova.test(groups = 4, n = 5, between.var = 1, within.var = 3)
# Power = 0.3535594

power.anova.test(groups = 4, between.var = 1, within.var = 3,
                  power = .80)
# n = 11.92613

## Assume we have prior knowledge of the group means:
groupmeans <- c(120, 130, 140, 150)
power.anova.test(groups = length(groupmeans),
                  between.var = var(groupmeans),
                  within.var = 500, power = .90) # n = 15.18834
```

---

power.prop.test

*Power Calculations for Two-Sample Test for Proportions*

---

**Description**

Compute the power of the two-sample test for proportions, or determine parameters to obtain a target power.

**Usage**

```
power.prop.test(n = NULL, p1 = NULL, p2 = NULL, sig.level = 0.05,
                power = NULL,
                alternative = c("two.sided", "one.sided"),
                strict = FALSE, tol = .Machine$double.eps^0.25)
```

## Arguments

|             |                                                                                                     |
|-------------|-----------------------------------------------------------------------------------------------------|
| n           | number of observations (per group)                                                                  |
| p1          | probability in one group                                                                            |
| p2          | probability in other group                                                                          |
| sig.level   | significance level (Type I error probability)                                                       |
| power       | power of test (1 minus Type II error probability)                                                   |
| alternative | one- or two-sided test. Can be abbreviated.                                                         |
| strict      | use strict interpretation in two-sided case                                                         |
| tol         | numerical tolerance used in root finding, the default providing (at least) four significant digits. |

## Details

Exactly one of the parameters `n`, `p1`, `p2`, `power`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that `sig.level` has a non-`NULL` default so `NULL` must be explicitly passed if you want it computed.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

## Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

### Note

uniroot is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given. If one of them is computed  $p_1 < p_2$  will hold, although this is not enforced when both are specified.

**Author(s)**

Peter Dalgaard. Based on previous work by Claus Ekstrøm

## Examples

```
power.prop.test(n = 50, p1 = .50, p2 = .75)      ## => power = 0.740
power.prop.test(p1 = .50, p2 = .75, power = .90) ## =>    n = 76.7
power.prop.test(n = 50, p1 = .5, power = .90)    ## =>    p2 = 0.8026
power.prop.test(n = 50, p1 = .5, p2 = 0.9, power = .90, sig.level=NULL) ## => sig.l = 0.00131
power.prop.test(p1 = .5, p2 = 0.501, sig.level=.001, power=0.90)      ## => n = 10451937
```

power.t.test

*Power calculations for one and two sample t tests***Description**

Compute the power of the one- or two- sample t test, or determine parameters to obtain a target power.

**Usage**

```
power.t.test(n = NULL, delta = NULL, sd = 1, sig.level = 0.05,
             power = NULL,
             type = c("two.sample", "one.sample", "paired"),
             alternative = c("two.sided", "one.sided"),
             strict = FALSE, tol = .Machine$double.eps^0.25)
```

**Arguments**

|             |                                                                                                     |
|-------------|-----------------------------------------------------------------------------------------------------|
| n           | number of observations (per group)                                                                  |
| delta       | true difference in means                                                                            |
| sd          | standard deviation                                                                                  |
| sig.level   | significance level (Type I error probability)                                                       |
| power       | power of test (1 minus Type II error probability)                                                   |
| type        | string specifying the type of t test. Can be abbreviated.                                           |
| alternative | one- or two-sided test. Can be abbreviated.                                                         |
| strict      | use strict interpretation in two-sided case                                                         |
| tol         | numerical tolerance used in root finding, the default providing (at least) four significant digits. |

**Details**

Exactly one of the parameters n, delta, power, sd, and sig.level must be passed as NULL, and that parameter is determined from the others. Notice that the last two have non-NULL defaults, so NULL must be explicitly passed if you want to compute them.

If strict = TRUE is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

**Value**

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

**Note**

uniroot is used to solve the power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

power.t.test(power = .90, delta = 1)
power.t.test(power = .90, delta = 1, alternative = "one.sided")
```

---

 PP.test

---

*Phillips-Perron Test for Unit Roots*

---

**Description**

Computes the Phillips-Perron test for the null hypothesis that  $x$  has a unit root against a stationary alternative.

**Usage**

```
PP.test(x, lshort = TRUE)
```

**Arguments**

|                     |                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------|
| <code>x</code>      | a numeric vector or univariate time series.                                                     |
| <code>lshort</code> | a logical indicating whether the short or long version of the truncation lag parameter is used. |

**Details**

The general regression equation which incorporates a constant and a linear trend is used and the corrected t-statistic for a first order autoregressive coefficient equals one is computed. To estimate  $\sigma^2$  the Newey-West estimator is used. If `lshort` is TRUE, then the truncation lag parameter is set to  $\text{trunc}(4*(n/100)^{0.25})$ , otherwise  $\text{trunc}(12*(n/100)^{0.25})$  is used. The p-values are interpolated from Table 4.2, page 103 of Banerjee *et al* (1993).

Missing values are not handled.

**Value**

A list with class "htest" containing the following components:

|           |                                                                |
|-----------|----------------------------------------------------------------|
| statistic | the value of the test statistic.                               |
| parameter | the truncation lag parameter.                                  |
| p.value   | the p-value of the test.                                       |
| method    | a character string indicating what type of test was performed. |
| data.name | a character string giving the name of the data.                |

**Examples**

```
x <- rnorm(1000)
PP.test(x)
y <- cumsum(x) # has unit root
PP.test(y)
```

---

ppoints

---

*Ordinates for Probability Plotting*

---

**Description**

Generates the sequence of probability points  $(1:m - a)/(m + (1-a)-a)$  where  $m$  is either  $n$ , if  $\text{length}(n)=1$ , or  $\text{length}(n)$ .

**Usage**

```
ppoints(n, a = ifelse(n <= 10, 3/8, 1/2))
```

**Arguments**

|   |                                                                    |
|---|--------------------------------------------------------------------|
| n | either the number of points generated or a vector of observations. |
| a | the offset fraction to be used; typically in $(0, 1)$ .            |

## Details

If  $0 < a < 1$ , the resulting values are within  $(0, 1)$  (excluding boundaries). In any case, the resulting sequence is symmetric in  $[0, 1]$ , i.e.,  $p + \text{rev}(p) == 1$ .

`ppoints()` is used in `qqplot` and `qqnorm` to generate the set of probabilities at which to evaluate the inverse distribution.

The choice of `a` follows the documentation of the function of the same name in Becker *et al* (1988), and appears to have been motivated by results from Blom (1958) on approximations to expect normal order statistics (see also [quantile](#)).

ppr

*Projection Pursuit Regression*

---

## Description

Fit a projection pursuit regression model.

## Usage

```
ppr(x, ...)

## S3 method for class 'formula'
ppr(formula, data, weights, subset, na.action,
     contrasts = NULL, ..., model = FALSE)

## Default S3 method:
ppr(x, y, weights = rep(1, n),
     ww = rep(1, q), nterms, max.terms = nterms, optlevel = 2,
     sm.method = c("supsmu", "spline", "gcv spline"),
     bass = 0, span = 0, df = 5, gcvpen = 1, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | a formula specifying one or more numeric response variables and the explanatory variables.                                                                                                                                                                                                                                                                                      |
| <code>x</code>         | numeric matrix of explanatory variables. Rows represent observations, and columns represent variables. Missing values are not accepted.                                                                                                                                                                                                                                         |
| <code>y</code>         | numeric matrix of response variables. Rows represent observations, and columns represent variables. Missing values are not accepted.                                                                                                                                                                                                                                            |
| <code>nterms</code>    | number of terms to include in the final model.                                                                                                                                                                                                                                                                                                                                  |
| <code>data</code>      | a data frame (or similar: see <a href="#">model.frame</a> ) from which variables specified in <code>formula</code> are preferentially to be taken.                                                                                                                                                                                                                              |
| <code>weights</code>   | a vector of weights $w_i$ for each <i>case</i> .                                                                                                                                                                                                                                                                                                                                |
| <code>ww</code>        | a vector of weights for each <i>response</i> , so the fit criterion is the sum over case $i$ and responses $j$ of $w_i ww_j (y_{ij} - \text{fit}_{ij})^2$ divided by the sum of $w_i$ .                                                                                                                                                                                         |
| <code>subset</code>    | an index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)                                                                                                                                                                                                                                                          |
| <code>na.action</code> | a function to specify the action to be taken if <b>NA</b> s are found. The default action is given by <code>getOption("na.action")</code> . (NOTE: If given, this argument must be named.)                                                                                                                                                                                      |
| <code>contrasts</code> | the contrasts to be used when any factor explanatory variables are coded.                                                                                                                                                                                                                                                                                                       |
| <code>max.terms</code> | maximum number of terms to choose from when building the model.                                                                                                                                                                                                                                                                                                                 |
| <code>optlevel</code>  | integer from 0 to 3 which determines the thoroughness of an optimization routine in the SMART program. See the ‘Details’ section.                                                                                                                                                                                                                                               |
| <code>sm.method</code> | the method used for smoothing the ridge functions. The default is to use Friedman’s super smoother <code>supsmu</code> . The alternatives are to use the smoothing spline code underlying <code>smooth.spline</code> , either with a specified (equivalent) degrees of freedom for each ridge functions, or to allow the smoothness to be chosen by GCV.<br>Can be abbreviated. |
| <code>bass</code>      | super smoother bass tone control used with automatic span selection (see <code>supsmu</code> ); the range of values is 0 to 10, with larger values resulting in increased smoothing.                                                                                                                                                                                            |
| <code>span</code>      | super smoother span control (see <code>supsmu</code> ). The default, 0, results in automatic span selection by local cross validation. <code>span</code> can also take a value in $(0, 1]$ .                                                                                                                                                                                    |
| <code>df</code>        | if <code>sm.method</code> is "spline" specifies the smoothness of each ridge term via the requested equivalent degrees of freedom.                                                                                                                                                                                                                                              |
| <code>gcvpen</code>    | if <code>sm.method</code> is "gcv spline" this is the penalty used in the GCV selection for each degree of freedom used.                                                                                                                                                                                                                                                        |
| <code>...</code>       | arguments to be passed to or from other methods.                                                                                                                                                                                                                                                                                                                                |
| <code>model</code>     | logical. If true, the model frame is returned.                                                                                                                                                                                                                                                                                                                                  |

## Details

The basic method is given by Friedman (1984), and is essentially the same code used by S-PLUS's `ppreg`. This code is extremely sensitive to the compiler used.

The algorithm first adds up to `max.terms` ridge terms one at a time; it will use less if it is unable to find a term to add that makes sufficient difference. It then removes the least important term at each step until `nterms` terms are left.

The levels of optimization (argument `optlevel`) differ in how thoroughly the models are refitted during this process. At level 0 the existing ridge terms are not refitted. At level 1 the projection directions are not refitted, but the ridge functions and the regression coefficients are.

Levels 2 and 3 refit all the terms and are equivalent for one response; level 3 is more careful to re-balance the contributions from each regressor at each step and so is a little less likely to converge to a saddle point of the sum of squares criterion.

## Value

A list with the following components, many of which are for use by the method functions.

|                            |                                                                                                                                                                           |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>call</code>          | the matched call                                                                                                                                                          |
| <code>p</code>             | the number of explanatory variables (after any coding)                                                                                                                    |
| <code>q</code>             | the number of response variables                                                                                                                                          |
| <code>mu</code>            | the argument <code>nterms</code>                                                                                                                                          |
| <code>ml</code>            | the argument <code>max.terms</code>                                                                                                                                       |
| <code>gof</code>           | the overall residual (weighted) sum of squares for the selected model                                                                                                     |
| <code>gofn</code>          | the overall residual (weighted) sum of squares against the number of terms, up to <code>max.terms</code> . Will be invalid (and zero) for less than <code>nterms</code> . |
| <code>df</code>            | the argument <code>df</code>                                                                                                                                              |
| <code>edf</code>           | if <code>sm.method</code> is "spline" or "gcv spline" the equivalent number of degrees of freedom for each ridge term used.                                               |
| <code>xnames</code>        | the names of the explanatory variables                                                                                                                                    |
| <code>yname</code> s       | the names of the response variables                                                                                                                                       |
| <code>alpha</code>         | a matrix of the projection directions, with a column for each ridge term                                                                                                  |
| <code>beta</code>          | a matrix of the coefficients applied for each response to the ridge terms: the rows are the responses and the columns the ridge terms                                     |
| <code>yb</code>            | the weighted means of each response                                                                                                                                       |
| <code>ys</code>            | the overall scale factor used: internally the responses are divided by <code>ys</code> to have unit total weighted sum of squares.                                        |
| <code>fitted.values</code> | the fitted values, as a matrix if <code>q &gt; 1</code> .                                                                                                                 |
| <code>residuals</code>     | the residuals, as a matrix if <code>q &gt; 1</code> .                                                                                                                     |
| <code>smod</code>          | internal work array, which includes the ridge functions evaluated at the training set points.                                                                             |
| <code>model</code>         | (only if <code>model = TRUE</code> ) the model frame.                                                                                                                     |

detach()
```

prcomp

*Principal Components Analysis*

## Description

Performs a principal components analysis on the given data matrix and returns the results as an object of class `prcomp`.

## Usage

```
prcomp(x, ...)

## S3 method for class 'formula'
prcomp(formula, data = NULL, subset, na.action, ...)

## Default S3 method:
prcomp(x, retx = TRUE, center = TRUE, scale. = FALSE,
       tol = NULL, ...)

## S3 method for class 'prcomp'
predict(object, newdata, ...)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | a formula with no response variable, referring only to numeric variables.                                                                                                                                                                                                |
| <code>data</code>      | an optional data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .                                                         |
| <code>subset</code>    | an optional vector used to select rows (observations) of the data matrix <code>x</code> .                                                                                                                                                                                |
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of <a href="#">options</a> , and is <a href="#">na.fail</a> if that is unset. The ‘factory-fresh’ default is <a href="#">na.omit</a> . |
| <code>...</code>       | arguments passed to or from other methods. If <code>x</code> is a formula one might specify <code>scale.</code> or <code>tol</code> .                                                                                                                                    |
| <code>x</code>         | a numeric or complex matrix (or data frame) which provides the data for the principal components analysis.                                                                                                                                                               |
| <code>retx</code>      | a logical value indicating whether the rotated variables should be returned.                                                                                                                                                                                             |
| <code>center</code>    | a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of <code>x</code> can be supplied. The value is passed to <code>scale</code> .                                       |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>scale.</code>  | a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is FALSE for consistency with <code>S</code> , but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of <code>x</code> can be supplied. The value is passed to <code>scale</code> .                                                                                             |
| <code>tol</code>     | a value indicating the magnitude below which components should be omitted. (Components are omitted if their standard deviations are less than or equal to <code>tol</code> times the standard deviation of the first component.) With the default null setting, no components are omitted. Other settings for <code>tol</code> could be <code>tol = 0</code> or <code>tol = sqrt(.Machine\$double.eps)</code> , which would omit essentially constant components. |
| <code>object</code>  | Object of class inheriting from "prcomp"                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>newdata</code> | An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, <code>newdata</code> must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.                                                                                                      |

### Details

The calculation is done by a singular value decomposition of the (centered and possibly scaled) data matrix, not by using `eigen` on the covariance matrix. This is generally the preferred method for numerical accuracy. The `print` method for these objects prints the results in a nice format and the `plot` method produces a scree plot.

Unlike `princomp`, variances are computed with the usual divisor  $N - 1$ .

Note that `scale = TRUE` cannot be used if there are zero or constant (for `center = TRUE`) variables.

### Value

`prcomp` returns a list with class "prcomp" containing the following components:

|                            |                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sdev</code>          | the standard deviations of the principal components (i.e., the square roots of the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix).                                                                                                                                                 |
| <code>rotation</code>      | the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). The function <code>princomp</code> returns this in the element <code>loadings</code> .                                                                                                                                                                                            |
| <code>x</code>             | if <code>retx</code> is true the value of the rotated data (the centred (and scaled if requested) data multiplied by the rotation matrix) is returned. Hence, <code>cov(x)</code> is the diagonal matrix <code>diag(sdev^2)</code> . For the formula method, <code>napredict()</code> is applied to handle the treatment of values omitted by the <code>na.action</code> . |
| <code>center, scale</code> | the centering and scaling used, or FALSE.                                                                                                                                                                                                                                                                                                                                  |

### Note

The signs of the columns of the rotation matrix are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

predict

*Model Predictions*

---

## Description

`predict` is a generic function for predictions from the results of various model fitting functions. The function invokes particular *methods* which depend on the [class](#) of the first argument.

## Usage

```
predict (object, ...)
```

## Arguments

|                     |                                                          |
|---------------------|----------------------------------------------------------|
| <code>object</code> | a model object for which prediction is desired.          |
| <code>...</code>    | additional arguments affecting the predictions produced. |

## Details

Most prediction methods which are similar to those for linear models have an argument `newdata` specifying the first place to look for explanatory variables to be used for prediction. Some considerable attempts are made to match up the columns in `newdata` to those used for fitting, for example that they are of comparable types and that any factors have the same level set in the same order (or can be transformed to be so).

Time series prediction methods in package **stats** have an argument `n.ahead` specifying how many time steps ahead to predict.

Many methods have a logical argument `se.fit` saying if standard errors are to be returned.

## Value

The form of the value returned by `predict` depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

|               |                                 |
|---------------|---------------------------------|
| predict.Arima | <i>Forecast from ARIMA fits</i> |
|---------------|---------------------------------|

---

## Description

Forecast from models fitted by [arima](#).

## Usage

```
## S3 method for class 'Arima'
predict(object, n.ahead = 1, newxreg = NULL,
        se.fit = TRUE, ...)
```

## Arguments

|         |                                                                                |
|---------|--------------------------------------------------------------------------------|
| object  | The result of an arima fit.                                                    |
| n.ahead | The number of steps ahead for which prediction is required.                    |
| newxreg | New values of xreg to be used for prediction. Must have at least n.ahead rows. |
| se.fit  | Logical: should standard errors of prediction be returned?                     |
| ...     | arguments passed to or from other methods.                                     |

## Details

Finite-history prediction is used, via [KalmanForecast](#). This is only statistically efficient if the MA part of the fit is invertible, so `predict.Arima` will give a warning for non-invertible MA models.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients. According to Harvey (1993, pp. 58–9) the effect is small.

## Value

A time series of predictions, or if `se.fit = TRUE`, a list with components `pred`, the predictions, and `se`, the estimated standard errors. Both components are time series.

predict.glm

*Predict Method for GLM Fits***Description**

Obtains predictions and optionally estimates standard errors of those predictions from a fitted generalized linear model object.

**Usage**

```
## S3 method for class 'glm'
predict(object, newdata = NULL,
        type = c("link", "response", "terms"),
        se.fit = FALSE, dispersion = NULL, terms = NULL,
        na.action = na.pass, ...)
```

**Arguments**

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object     | a fitted object of class inheriting from "glm".                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| newdata    | optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.                                                                                                                                                                                                                                                                                                                                                                             |
| type       | the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities. The "terms" option returns a matrix giving the fitted values of each term in the model formula on the linear predictor scale.<br>The value of this argument can be abbreviated. |
| se.fit     | logical switch indicating if standard errors are required.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| dispersion | the dispersion of the GLM fit to be assumed in computing the standard errors. If omitted, that returned by summary applied to the object is used.                                                                                                                                                                                                                                                                                                                                                             |
| terms      | with type = "terms" by default all terms are returned. A character vector specifies which terms are to be returned                                                                                                                                                                                                                                                                                                                                                                                            |
| na.action  | function determining what should be done with missing values in newdata. The default is to predict NA.                                                                                                                                                                                                                                                                                                                                                                                                        |
| ...        | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Details

If newdata is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear (in predictions and standard errors), with residual value NA. See also [napredict](#).

## Value

If se.fit = FALSE, a vector or matrix of predictions. For type = "terms" this is a matrix with a column per term, and may have an attribute "constant".

If se.fit = TRUE, a list with components

|                |                                                                                          |
|----------------|------------------------------------------------------------------------------------------|
| fit            | Predictions, as for se.fit = FALSE.                                                      |
| se.fit         | Estimated standard errors.                                                               |
| residual.scale | A scalar giving the square root of the dispersion used in computing the standard errors. |

## Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

---

predict.HoltWinters      *Prediction Function for Fitted Holt-Winters Models*

---

### Description

Computes predictions and prediction intervals for models fitted by the Holt-Winters method.

### Usage

```
## S3 method for class 'HoltWinters'
predict(object, n.ahead = 1, prediction.interval = FALSE,
        level = 0.95, ...)
```

### Arguments

|                     |                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------|
| object              | An object of class HoltWinters.                                                                      |
| n.ahead             | Number of future periods to predict.                                                                 |
| prediction.interval | logical. If TRUE, the lower and upper bounds of the corresponding prediction intervals are computed. |
| level               | Confidence level for the prediction interval.                                                        |
| ...                 | arguments passed to or from other methods.                                                           |

### Value

A time series of the predicted values. If prediction intervals are requested, a multiple time series is returned with columns `fit`, `lwr` and `upr` for the predicted values and the lower and upper bounds respectively.

*Predict method for Linear Model Fits***Description**

Predicted values based on linear model object.

**Usage**

```
## S3 method for class 'lm'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
        interval = c("none", "confidence", "prediction"),
        level = 0.95, type = c("response", "terms"),
        terms = NULL, na.action = na.pass,
        pred.var = res.var/weights, weights = 1, ...)
```

**Arguments**

|           |                                                                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | Object of class inheriting from "lm"                                                                                                                                     |
| newdata   | An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.                                                     |
| se.fit    | A switch indicating if standard errors are required.                                                                                                                     |
| scale     | Scale parameter for std.err. calculation.                                                                                                                                |
| df        | Degrees of freedom for scale.                                                                                                                                            |
| interval  | Type of interval calculation. Can be abbreviated.                                                                                                                        |
| level     | Tolerance/confidence level.                                                                                                                                              |
| type      | Type of prediction (response or model term). Can be abbreviated.                                                                                                         |
| terms     | If type = "terms", which terms (default is all terms), a <a href="#">character</a> vector.                                                                               |
| na.action | function determining what should be done with missing values in newdata. The default is to predict NA.                                                                   |
| pred.var  | the variance(s) for future observations to be assumed for prediction intervals. See 'Details'.                                                                           |
| weights   | variance weights for prediction. This can be a numeric vector or a one-sided model formula. In the latter case, it is interpreted as an expression evaluated in newdata. |
| ...       | further arguments passed to or from other methods.                                                                                                                       |

## Details

`predict.lm` produces predicted values, obtained by evaluating the regression function in the frame `newdata` (which defaults to `model.frame(object)`). If the logical `se.fit` is `TRUE`, standard errors of the predictions are calculated. If the numeric argument `scale` is set (with optional `df`), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting `intervals` specifies computation of confidence or prediction (tolerance) intervals at the specified level, sometimes referred to as narrow vs. wide intervals.

If the fit is rank-deficient, some of the columns of the design matrix will have been dropped. Prediction from such a fit only makes sense if `newdata` is contained in the same subspace as the original data. That cannot be checked accurately, so a warning is issued.

If `newdata` is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit are handled is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the predictions, whereas if `na.action = na.exclude` they will appear (in predictions, standard errors or interval limits), with value `NA`. See also [napredict](#).

The prediction intervals are for a single observation at each case in `newdata` (or by default, the data used for the fit) with error variance(s) `pred.var`. This can be a multiple of `res.var`, the estimated value of  $\sigma^2$ : the default is to assume that future observations have the same error variance as those used for fitting. If `weights` is supplied, the inverse of this is used as a scale factor. For a weighted fit, if the prediction is for the original data frame, `weights` defaults to the weights used for the model fit, with a warning since it might not be the intended result. If the fit was weighted and `newdata` is given, the default is to assume constant prediction variance, with a warning.

## Value

`predict.lm` produces a vector of predictions or a matrix of predictions and bounds with column names `fit`, `lwr`, and `upr` if `interval` is set. For `type = "terms"` this is a matrix with a column per term and may have an attribute `"constant"`.

If `se.fit` is `TRUE`, a list with the following components is returned:

|                             |                                   |
|-----------------------------|-----------------------------------|
| <code>fit</code>            | vector or matrix as above         |
| <code>se.fit</code>         | standard error of predicted means |
| <code>residual.scale</code> | residual standard deviations      |
| <code>df</code>             | degrees of freedom for residual   |

## Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

Notice that prediction variances and prediction intervals always refer to *future* observations, possibly corresponding to the same predictors as used for the fit. The variance of the *residuals* will be smaller.

Strictly speaking, the formula used for prediction limits assumes that the degrees of freedom for the fit are the same as those for the residual variance. This may not be the case if `res.var` is not obtained from the fit.

npk.aov <- aov(yield ~ block + N*P*K, npk)
(termL <- attr(terms(npk.aov), "term.labels"))
(pt <- predict(npk.aov, type = "terms"))
pt. <- predict(npk.aov, type = "terms", terms = termL[1:4])
stopifnot(all.equal(pt[,1:4], pt.,
                    tolerance = 1e-12, check.attributes = FALSE))
```

---

predict.loess

*Predict Loess Curve or Surface*

---

**Description**

Predictions from a loess fit, optionally with standard errors.

**Usage**

```
## S3 method for class 'loess'
predict(object, newdata = NULL, se = FALSE,
        na.action = na.pass, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>    | an object fitted by <code>loess</code> .                                                                                                                                                                  |
| <code>newdata</code>   | an optional data frame in which to look for variables with which to predict, or a matrix or vector containing exactly the variables needed for prediction. If missing, the original data points are used. |
| <code>se</code>        | should standard errors be computed?                                                                                                                                                                       |
| <code>na.action</code> | function determining what should be done with missing values in data frame <code>newdata</code> . The default is to predict NA.                                                                           |
| <code>...</code>       | arguments passed to or from other methods.                                                                                                                                                                |

**Details**

The standard errors calculation is slower than prediction.

When the fit was made using `surface = "interpolate"` (the default), `predict.loess` will not extrapolate – so points outside an axis-aligned hypercube enclosing the original data will have missing (NA) predictions and standard errors.

**Value**

If `se = FALSE`, a vector giving the prediction for each row of `newdata` (or the original data). If `se = TRUE`, a list containing components

|                             |                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fit</code>            | the predicted values.                                                                                                                      |
| <code>se</code>             | an estimated standard error for each predicted value.                                                                                      |
| <code>residual.scale</code> | the estimated scale of the residuals used in computing the standard errors.                                                                |
| <code>df</code>             | an estimate of the effective degrees of freedom used in estimating the residual scale, intended for use with t-based confidence intervals. |

If `newdata` was the result of a call to [expand.grid](#), the predictions (and s.e.'s if requested) will be an array of the appropriate dimensions.

Predictions from infinite inputs will be NA since `loess` does not support extrapolation.

**Note**

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

**Author(s)**

B. D. Ripley, based on the `cloess` package of Cleveland, Grosse and Shyu.

**See Also**

[loess](#)

**Examples**

```
cars.lo <- loess(dist ~ speed, cars)
predict(cars.lo, data.frame(speed = seq(5, 30, 1)), se = TRUE)
# to get extrapolation
cars.lo2 <- loess(dist ~ speed, cars,
  control = loess.control(surface = "direct"))
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)
```

predict.nls

*Predicting from Nonlinear Least Squares Fits***Description**

`predict.nls` produces predicted values, obtained by evaluating the regression function in the frame `newdata`. If the logical `se.fit` is `TRUE`, standard errors of the predictions are calculated. If the numeric argument `scale` is set (with optional `df`), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting `interval` specifies computation of confidence or prediction (tolerance) intervals at the specified level.

At present `se.fit` and `interval` are ignored.

**Usage**

```
## S3 method for class 'nls'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
  interval = c("none", "confidence", "prediction"),
  level = 0.95, ...)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                            |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>   | An object that inherits from class <code>nls</code> .                                                                                                                                                                                                      |
| <code>newdata</code>  | A named list or data frame in which to look for variables with which to predict. If <code>newdata</code> is missing the fitted values at the original data points are returned.                                                                            |
| <code>se.fit</code>   | A logical value indicating if the standard errors of the predictions should be calculated. Defaults to <code>FALSE</code> . At present this argument is ignored.                                                                                           |
| <code>scale</code>    | A numeric scalar. If it is set (with optional <code>df</code> ), it is used as the residual standard deviation in the computation of the standard errors, otherwise this information is extracted from the model fit. At present this argument is ignored. |
| <code>df</code>       | A positive numeric scalar giving the number of degrees of freedom for the scale estimate. At present this argument is ignored.                                                                                                                             |
| <code>interval</code> | A character string indicating if prediction intervals or a confidence interval on the mean responses are to be calculated. At present this argument is ignored.                                                                                            |
| <code>level</code>    | A numeric scalar between 0 and 1 giving the confidence level for the intervals (if any) to be calculated. At present this argument is ignored.                                                                                                             |
| <code>...</code>      | Additional optional arguments. At present no optional arguments are used.                                                                                                                                                                                  |

**Value**

predict.nls produces a vector of predictions. When implemented, interval will produce a matrix of predictions and bounds with column names fit, lwr, and upr. When implemented, if se.fit is TRUE, a list with the following components will be returned:

|                |                                 |
|----------------|---------------------------------|
| fit            | vector or matrix as above       |
| se.fit         | standard error of predictions   |
| residual.scale | residual standard deviations    |
| df             | degrees of freedom for residual |

**Note**

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

**Examples**

```
require(graphics)

fm <- nls(demand ~ SSasymOrig(Time, A, lrc), data = BOD)
predict(fm)           # fitted values at observed times
## Form data plot and smooth line for the predictions
opar <- par(las = 1)
plot(demand ~ Time, data = BOD, col = 4,
     main = "BOD data and fitted first-order curve",
     xlim = c(0,7), ylim = c(0, 20) )
tt <- seq(0, 8, length = 101)
lines(tt, predict(fm, list(Time = tt)))
par(opar)
```

---

predict.smooth.spline *Predict from Smoothing Spline Fit*

---

**Description**

Predict a smoothing spline fit at new points, return the derivative if desired. The predicted fit is linear beyond the original data.

**Usage**

```
## S3 method for class 'smooth.spline'
predict(object, x, deriv = 0, ...)
```

**Arguments**

|        |                                                    |
|--------|----------------------------------------------------|
| object | a fit from smooth.spline.                          |
| x      | the new values of x.                               |
| deriv  | integer; the order of the derivative required.     |
| ...    | further arguments passed to or from other methods. |

**Value**

A list with components

|   |                                        |
|---|----------------------------------------|
| x | The input x.                           |
| y | The fitted values or derivatives at x. |

**See Also**

```
preplot
```

---

```
Pre-computations for a Plotting Object
```

---

### Description

Compute an object to be used for plots relating to the given model object.

### Usage

```
preplot(object, ...)
```

### Arguments

|                     |                                            |
|---------------------|--------------------------------------------|
| <code>object</code> | a fitted model object.                     |
| <code>...</code>    | additional arguments for specific methods. |

### Details

Only the generic function is currently provided in base R, but some add-on packages have methods. Principally here for S compatibility.

### Value

An object set up to make a plot that describes object.

---

```
princomp
```

---

```
Principal Components Analysis
```

---

### Description

`princomp` performs a principal components analysis on the given numeric data matrix and returns the results as an object of class `princomp`.

### Usage

```
princomp(x, ...)

## S3 method for class 'formula'
princomp(formula, data = NULL, subset, na.action, ...)

## Default S3 method:
princomp(x, cor = FALSE, scores = TRUE, covmat = NULL,
         subset = rep_len(TRUE, nrow(as.matrix(x))), ...)

## S3 method for class 'princomp'
predict(object, newdata, ...)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula with no response variable, referring only to numeric variables.                                                                                                                                                                                                                                                                                    |
| data      | an optional data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula formula. By default the variables are taken from <code>environment(formula)</code> .                                                                                                                                                           |
| subset    | an optional vector used to select rows (observations) of the data matrix <code>x</code> .                                                                                                                                                                                                                                                                    |
| na.action | a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of <a href="#">options</a> , and is <code>na.fail</code> if that is unset. The ‘factory-fresh’ default is <code>na.omit</code> .                                                                                           |
| x         | a numeric matrix or data frame which provides the data for the principal components analysis.                                                                                                                                                                                                                                                                |
| cor       | a logical value indicating whether the calculation should use the correlation matrix or the covariance matrix. (The correlation matrix can only be used if there are no constant variables.)                                                                                                                                                                 |
| scores    | a logical value indicating whether the score on each principal component should be calculated.                                                                                                                                                                                                                                                               |
| covmat    | a covariance matrix, or a covariance list as returned by <a href="#">cov.wt</a> (and <a href="#">cov.mve</a> or <a href="#">cov.mcd</a> from package <b>MASS</b> ). If supplied, this is used rather than the covariance matrix of <code>x</code> .                                                                                                          |
| ...       | arguments passed to or from other methods. If <code>x</code> is a formula one might specify <code>cor</code> or <code>scores</code> .                                                                                                                                                                                                                        |
| object    | Object of class inheriting from "princomp"                                                                                                                                                                                                                                                                                                                   |
| newdata   | An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, <code>newdata</code> must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order. |

## Details

`princomp` is a generic function with "formula" and "default" methods.

The calculation is done using [eigen](#) on the correlation or covariance matrix, as determined by `cor`. This is done for compatibility with the S-PLUS result. A preferred method of calculation is to use [svd](#) on `x`, as is done in `prcomp`.

Note that the default calculation uses divisor `N` for the covariance matrix.

The [print](#) method for these objects prints the results in a nice format and the [plot](#) method produces a scree plot ([screeplot](#)). There is also a [biplot](#) method.

If `x` is a formula then the standard NA-handling is applied to the scores (if requested): see [napredict](#).

`princomp` only handles so-called R-mode PCA, that is feature extraction of variables. If a data matrix is supplied (possibly via a formula) it is required that there are at least as many units as variables. For Q-mode PCA use [prcomp](#).

**Value**

princomp returns a list with class "princomp" containing the following components:

|           |                                                                                                                                                                                                                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sdev      | the standard deviations of the principal components.                                                                                                                                                                                                                                                              |
| loadings  | the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). This is of class "loadings": see <a href="#">loadings</a> for its print method.                                                                                                                                          |
| center    | the means that were subtracted.                                                                                                                                                                                                                                                                                   |
| scale     | the scalings applied to each variable.                                                                                                                                                                                                                                                                            |
| n.obs     | the number of observations.                                                                                                                                                                                                                                                                                       |
| scores    | if scores = TRUE, the scores of the supplied data on the principal components. These are non-null only if x was supplied, and if covmat was also supplied if it was a covariance list. For the formula method, <a href="#">napredict()</a> is applied to handle the treatment of values omitted by the na.action. |
| call      | the matched call.                                                                                                                                                                                                                                                                                                 |
| na.action | If relevant.                                                                                                                                                                                                                                                                                                      |

**Note**

The signs of the columns of the loadings and scores are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

**Examples**

```
require(graphics)

## The variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests)) # inappropriate
princomp(USArrests, cor = TRUE) # ^= prcomp(USArrests, scale=TRUE)
## Similar, but different:
## The standard deviations differ by a factor of sqrt(49/50)

summary(pc.cr <- princomp(USArrests, cor = TRUE))
loadings(pc.cr) # note that blank entries are small but not zero
## The signs of the columns are arbitrary
plot(pc.cr) # shows a screeplot.
biplot(pc.cr)

## Formula interface
```

```

princomp(~ ., data = USArrests, cor = TRUE)

## NA-handling
USArrests[1, 2] <- NA
pc.cr <- princomp(~ Murder + Assault + UrbanPop,
                  data = USArrests, na.action = na.exclude, cor = TRUE)
pc.cr$scores[1:5, ]

## (Simple) Robust PCA:
## Classical:
(pc.cl <- princomp(stackloss))
## Robust:
(pc.rob <- princomp(stackloss, covmat = MASS::cov.rob(stackloss)))

|-------------------|-------------------------------------------------------------------------|
| print.power.htest | <i>Print Methods for Hypothesis Tests and Power Calculation Objects</i> |
|-------------------|-------------------------------------------------------------------------|

---

## Description

Printing objects of class "htest" or "power.htest", respectively, by simple [print](#) methods.

## Usage

```

## S3 method for class 'htest'
print(x, digits = getOption("digits"), prefix = "\t", ...)

## S3 method for class 'power.htest'
print(x, digits = getOption("digits"), ...)

```

## Arguments

|        |                                                                                                    |
|--------|----------------------------------------------------------------------------------------------------|
| x      | object of class "htest" or "power.htest".                                                          |
| digits | number of significant digits to be used.                                                           |
| prefix | string, passed to <a href="#">strwrap</a> for displaying the method component of the htest object. |
| ...    | further arguments to be passed to or from methods.                                                 |

## Details

Both [print](#) methods traditionally have not obeyed the digits argument properly. They now do, the htest method mostly in expressions like `max(1, digits - 2)`.

A power.htest object is just a named list of numbers and character strings, supplemented with method and note elements. The method is displayed as a title, the note as a footnote, and the remaining elements are given in an aligned 'name = value' format.

## Value

the argument x, invisibly, as for all [print](#) methods.

**Author(s)**

Peter Dalgaard

**See Also**[power.t.test](#), [power.prop.test](#)**Examples**

```
(ptt <- power.t.test(n = 20, delta = 1))
print(ptt, digits = 4) # using less digits than default
print(ptt, digits = 12) # using more " " "
```

print.ts

*Printing and Formatting of Time-Series Objects***Description**

Notably for calendar related time series objects, [format](#) and [print](#) methods showing years, months and or quarters respectively.

**Usage**

```
## S3 method for class 'ts'
print(x, calendar, ...)

```

**Arguments**

|          |                                                                                                                                                                    |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x        | a time series object.                                                                                                                                              |
| calendar | enable/disable the display of information about month names, quarter names or year when printing. The default is TRUE for a frequency of 4 or 12, FALSE otherwise. |
| ...      | additional arguments to <a href="#">print</a> (or <a href="#">format</a> methods).                                                                                 |

**Details**

The [print](#) method for "ts" objects prints a header (basically of [tsp\(x\)](#)), if calendar is false, and then prints the result of `preformat.ts(x, *)`, which is typically a [matrix](#) with [rownames](#) built from the calendar times where applicable.

**See Also**[print](#), [ts](#).

## Examples

```
print(ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)

print(sunsp.1 <- window(sunspot.month, end=c(1756, 12)))
m <- .preformat.ts(sunsp.1) # a character matrix
```

|              |                                   |
|--------------|-----------------------------------|
| printCoefmat | <i>Print Coefficient Matrices</i> |
|--------------|-----------------------------------|

---

## Description

Utility function to be used in higher-level [print](#) methods, such as those for [summary.lm](#), [summary.glm](#) and [anova](#). The goal is to provide a flexible interface with smart defaults such that often, only `x` needs to be specified.

## Usage

```
printCoefmat(x, digits = max(3, getOption("digits") - 2),
             signif.stars = getOption("show.signif.stars"),
             signif.legend = signif.stars,
             dig.tst = max(1, min(5, digits - 1)),
             cs.ind = 1L:k, tst.ind = k + 1L,
             zap.ind = integer(), P.values = NULL,
             has.Pvalue = nc >= 4L &&
               substr(colnames(x)[nc], 1L, 3L) == "Pr(",
             eps.Pvalue = .Machine$double.eps,
             na.print = "NA", ...)
```

## Arguments

|                            |                                                                                                                                                                                                                                |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>             | a numeric matrix like object, to be printed.                                                                                                                                                                                   |
| <code>digits</code>        | minimum number of significant digits to be used for most numbers.                                                                                                                                                              |
| <code>signif.stars</code>  | logical; if TRUE, P-values are additionally encoded visually as ‘significance stars’ in order to help scanning of long coefficient tables. It defaults to the <code>show.signif.stars</code> slot of <a href="#">options</a> . |
| <code>signif.legend</code> | logical; if TRUE, a legend for the ‘significance stars’ is printed provided <code>signif.stars = TRUE</code> .                                                                                                                 |
| <code>dig.tst</code>       | minimum number of significant digits for the test statistics, see <code>tst.ind</code> .                                                                                                                                       |
| <code>cs.ind</code>        | indices (integer) of column numbers which are (like) coefficients and standard errors to be formatted together.                                                                                                                |
| <code>tst.ind</code>       | indices (integer) of column numbers for test statistics.                                                                                                                                                                       |
| <code>zap.ind</code>       | indices (integer) of column numbers which should be formatted by <a href="#">zapsmall</a> , i.e., by ‘zapping’ values close to 0.                                                                                              |

|                         |                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>P.values</code>   | logical or NULL; if TRUE, the last column of <code>x</code> is formatted by <code>format.pval</code> as P values. If <code>P.values = NULL</code> , the default, it is set to TRUE only if <code>options("show.coef.Pvalue")</code> is TRUE <i>and</i> <code>x</code> has at least 4 columns <i>and</i> the last column name of <code>x</code> starts with "Pr(". |
| <code>has.Pvalue</code> | logical; if TRUE, the last column of <code>x</code> contains P values; in that case, it is printed if and only if <code>P.values</code> (above) is true.                                                                                                                                                                                                          |
| <code>eps.Pvalue</code> | number, ..                                                                                                                                                                                                                                                                                                                                                        |
| <code>na.print</code>   | a character string to code NA values in printed output.                                                                                                                                                                                                                                                                                                           |
| <code>...</code>        | further arguments for <code>print</code> .                                                                                                                                                                                                                                                                                                                        |

**Value**

Invisibly returns its argument, `x`.

profile

*Generic Function for Profiling Models*

---

**Description**

Investigates behavior of objective function near the solution represented by `fitted`.

See documentation on method functions for further details.

**Usage**

```
profile(fitted, ...)
```

**Arguments**

fitted            the original fitted model object.  
 ...              additional parameters. See documentation on individual methods.

**Value**

A list with an element for each parameter being profiled. See the individual methods for further details.

**See Also**

[profile.nls](#), [profile.glm](#) in package **MASS**, ...

For profiling R code, see [Rprof](#).

---

|             |                                         |
|-------------|-----------------------------------------|
| profile.nls | <i>Method for Profiling nls Objects</i> |
|-------------|-----------------------------------------|

---

**Description**

Investigates the profile log-likelihood function for a fitted model of class "nls".

**Usage**

```
## S3 method for class 'nls'
profile(fitted, which = 1:npar, maxpts = 100, alphamax = 0.01,
       delta.t = cutoff/5, ...)
```

**Arguments**

fitted            the original fitted model object.  
 which            the original model parameters which should be profiled. This can be a numeric or character vector. By default, all non-linear parameters are profiled.  
 maxpts           maximum number of points to be used for profiling each parameter.  
 alphamax        highest significance level allowed for the profile t-statistics.  
 delta.t          suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.  
 ...              further arguments passed to or from other methods.

**Details**

The profile t-statistics is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

**Value**

A list with an element for each parameter being profiled. The elements are data-frames with two variables

`par.vals`            a matrix of parameter values for each fitted model.  
`tau`                the profile t-statistics.

**Author(s)**

Of the original version, Douglas M. Bates and Saikat DebRoy

**References**

**Examples**

```
# obtain the fitted object
fm1 <- nls(demand ~ SSasymptOrig(Time, A, lrc), data = BOD)
# get the profile for the fitted model: default level is too extreme
pr1 <- profile(fm1, alpha = 0.05)
# profiled values for the two parameters
pr1$A
pr1$lrc
# see also example(plot.profile.nls)
```

---

proj

*Projections of Models*

---

**Description**

`proj` returns a matrix or list of matrices giving the projections of the data onto the terms of a linear model. It is most frequently used for [aov](#) models.

**Usage**

```
proj(object, ...)
```

## S3 method for class 'aov'

```
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)
```

```
## S3 method for class 'aovlist'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

## Default S3 method:
proj(object, onedf = TRUE, ...)

## S3 method for class 'lm'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)
```

## Arguments

|                  |                                                                                                                                                                                                                            |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object           | An object of class "lm" or a class inheriting from it, or an object with a similar structure including in particular components qr and effects.                                                                            |
| onedf            | A logical flag. If TRUE, a projection is returned for all the columns of the model matrix. If FALSE, the single-column projections are collapsed by terms of the model (as represented in the analysis of variance table). |
| unweighted.scale | If the fit producing object used weights, this determines if the projections correspond to weighted or unweighted observations.                                                                                            |
| ...              | Swallow and ignore any other arguments.                                                                                                                                                                                    |

## Details

A projection is given for each stratum of the object, so for aov models with an Error term the result is a list of projections.

## Value

A projection matrix or (for multi-stratum objects) a list of projection matrices.

Each projection is a matrix with a row for each observations and either a column for each term (onedf = FALSE) or for each coefficient (onedf = TRUE). Projection matrices from the default method have orthogonal columns representing the projection of the response onto the column space of the Q matrix from the QR decomposition. The fitted values are the sum of the projections, and the sum of squares for each column is the reduction in sum of squares from fitting that column (after those to the left of it).

The methods for lm and aov models add a column to the projection matrix giving the residuals (the projection of the data onto the orthogonal complement of the model space).

Strictly, when onedf = FALSE the result is not a projection, but the columns represent sums of projections onto the columns of the model matrix corresponding to that term. In this case the matrix does not depend on the coding used.

## Author(s)

The design was inspired by the S function of the same name described in Chambers *et al* (1992).

```

---

|           |                                           |
|-----------|-------------------------------------------|
| prop.test | <i>Test of Equal or Given Proportions</i> |
|-----------|-------------------------------------------|

---

Description

prop.test can be used for testing the null that the proportions (probabilities of success) in several groups are the same, or that they equal certain given values.

Usage

```
prop.test(x, n, p = NULL,
          alternative = c("two.sided", "less", "greater"),
          conf.level = 0.95, correct = TRUE)
```

Arguments

- x                    a vector of counts of successes, a one-dimensional table with two entries, or a two-dimensional table (or matrix) with 2 columns, giving the counts of successes and failures, respectively.
- n                    a vector of counts of trials; ignored if x is a matrix or a table.

|             |                                                                                                                                                                                                                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| p           | a vector of probabilities of success. The length of p must be the same as the number of groups specified by x, and its elements must be greater than 0 and less than 1.                                                                                                                           |
| alternative | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. Only used for testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise. |
| conf.level  | confidence level of the returned confidence interval. Must be a single number between 0 and 1. Only used when testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.                                                               |
| correct     | a logical indicating whether Yates' continuity correction should be applied where possible.                                                                                                                                                                                                       |

### Details

Only groups with finite numbers of successes and failures are used. Counts of successes and failures must be nonnegative and hence not greater than the corresponding numbers of trials which must be positive. All finite counts should be integers.

If p is NULL and there is more than one group, the null tested is that the proportions in each group are the same. If there are two groups, the alternatives are that the probability of success in the first group is less than, not equal to, or greater than the probability of success in the second group, as specified by alternative. A confidence interval for the difference of proportions with confidence level as specified by conf.level and clipped to  $[-1, 1]$  is returned. Continuity correction is used only if it does not exceed the difference of the sample proportions in absolute value. Otherwise, if there are more than 2 groups, the alternative is always "two.sided", the returned confidence interval is NULL, and continuity correction is never used.

If there is only one group, then the null tested is that the underlying probability of success is p, or .5 if p is not given. The alternative is that the probability of success is less than, not equal to, or greater than p or 0.5, respectively, as specified by alternative. A confidence interval for the underlying proportion with confidence level as specified by conf.level and clipped to  $[0, 1]$  is returned. Continuity correction is used only if it does not exceed the difference between sample and null proportions in absolute value. The confidence interval is computed by inverting the score test.

Finally, if p is given and there are more than 2 groups, the null tested is that the underlying probabilities of success are those given by p. The alternative is always "two.sided", the returned confidence interval is NULL, and continuity correction is never used.

### Value

A list with class "htest" containing the following components:

|           |                                                                                           |
|-----------|-------------------------------------------------------------------------------------------|
| statistic | the value of Pearson's chi-squared test statistic.                                        |
| parameter | the degrees of freedom of the approximate chi-squared distribution of the test statistic. |
| p.value   | the p-value of the test.                                                                  |
| estimate  | a vector with the sample proportions $x/n$ .                                              |

|             |                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| conf.int    | a confidence interval for the true proportion if there is one group, or for the difference in proportions if there are 2 groups and p is not given, or NULL otherwise. In the cases where it is not NULL, the returned confidence interval has an asymptotic confidence level as specified by conf.level, and is appropriate to the specified alternative hypothesis. |
| null.value  | the value of p if specified by the null, or NULL otherwise.                                                                                                                                                                                                                                                                                                           |
| alternative | a character string describing the alternative.                                                                                                                                                                                                                                                                                                                        |
| method      | a character string indicating the method used, and whether Yates' continuity correction was applied.                                                                                                                                                                                                                                                                  |
| data.name   | a character string giving the names of the data.                                                                                                                                                                                                                                                                                                                      |

|-----------------|--------------------------------------|
| prop.trend.test | <i>Test for trend in proportions</i> |
|-----------------|--------------------------------------|

---

## Description

Performs chi-squared test for trend in proportions, i.e., a test asymptotically optimal for local alternatives where the log odds vary in proportion with score. By default, score is chosen as the group numbers.

**Usage**

```
prop.trend.test(x, n, score = seq_along(x))
```

**Arguments**

|       |                  |
|-------|------------------|
| x     | Number of events |
| n     | Number of trials |
| score | Group score      |

**Value**

An object of class "htest" with title, test statistic, p-value, etc.

**Note**

This really should get integrated with `prop.test`

**Author(s)**

Peter Dalgaard

**See Also**

[prop.test](#)

**Examples**

```
smokers <- c( 83, 90, 129, 70 )
patients <- c( 86, 93, 136, 82 )
prop.test(smokers, patients)
prop.trend.test(smokers, patients)
prop.trend.test(smokers, patients, c(0,0,0,1))
```

---

qqnorm

*Quantile-Quantile Plots*

---

**Description**

qqnorm is a generic function the default method of which produces a normal QQ plot of the values in y. qqline adds a line to a “theoretical”, by default normal, quantile-quantile plot which passes through the probs quantiles, by default the first and third quartiles.

qqplot produces a QQ plot of two datasets.

Graphical parameters may be given as arguments to qqnorm, qqplot and qqline.

**Usage**

```
qqnorm(y, ...)
## Default S3 method:
qqnorm(y, ylim, main = "Normal Q-Q Plot",
       xlab = "Theoretical Quantiles", ylab = "Sample Quantiles",
       plot.it = TRUE, datax = FALSE, ...)

qqline(y, datax = FALSE, distribution = qnorm,
       probs = c(0.25, 0.75), qtype = 7, ...)

qqplot(x, y, plot.it = TRUE, xlab = deparse(substitute(x)),
       ylab = deparse(substitute(y)), ...)
```

**Arguments**

|                               |                                                                                                                                |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                | The first sample for qqplot.                                                                                                   |
| <code>y</code>                | The second or only data sample.                                                                                                |
| <code>xlab, ylab, main</code> | plot labels. The <code>xlab</code> and <code>ylab</code> refer to the y and x axes respectively if <code>datax = TRUE</code> . |
| <code>plot.it</code>          | logical. Should the result be plotted?                                                                                         |
| <code>datax</code>            | logical. Should data values be on the x-axis?                                                                                  |
| <code>distribution</code>     | quantile function for reference theoretical distribution.                                                                      |
| <code>probs</code>            | numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.                  |
| <code>qtype</code>            | the type of quantile computation used in <a href="#">quantile</a> .                                                            |
| <code>ylim, ...</code>        | graphical parameters.                                                                                                          |

**Value**

For qqnorm and qqplot, a list with components

|                |                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------|
| <code>x</code> | The x coordinates of the points that were/would be plotted                                          |
| <code>y</code> | The original y vector, i.e., the corresponding y coordinates <i>including</i> <a href="#">NAs</a> . |

|------------|-------------------|
| quade.test | <i>Quade Test</i> |
|------------|-------------------|

---

Description

Performs a Quade test with unreplicated blocked data.

Usage

```
quade.test(y, ...)

## Default S3 method:
quade.test(y, groups, blocks, ...)

## S3 method for class 'formula'
quade.test(formula, data, subset, na.action, ...)
```

Arguments

|         |                                                                                                                                                                                                |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y       | either a numeric vector of data values, or a data matrix.                                                                                                                                      |
| groups  | a vector giving the group for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.                                     |
| blocks  | a vector giving the block for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.                                     |
| formula | a formula of the form $a \sim b \mid c$ , where a, b and c give the data values and corresponding groups and blocks, respectively.                                                             |
| data    | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula formula. By default the variables are taken from environment(formula). |

|           |                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------|
| subset    | an optional vector specifying a subset of observations to be used.                                                         |
| na.action | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> . |
| ...       | further arguments to be passed to or from methods.                                                                         |

### Details

`quade.test` can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in `y` for each combination of levels of groups and blocks) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of blocks, the location parameter of `y` is the same in each of the groups.

If `y` is a matrix, groups and blocks are obtained from the column and row indices, respectively. NA's are not allowed in groups or blocks; if `y` contains NA's, corresponding blocks are removed.

### Value

A list with class "htest" containing the following components:

|           |                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------|
| statistic | the value of Quade's F statistic.                                                                                       |
| parameter | a vector with the numerator and denominator degrees of freedom of the approximate F distribution of the test statistic. |
| p.value   | the p-value of the test.                                                                                                |
| method    | the character string "Quade test".                                                                                      |
| data.name | a character string giving the names of the data.                                                                        |

quantile

*Sample Quantiles***Description**

The generic function `quantile` produces sample quantiles corresponding to the given probabilities. The smallest observation corresponds to a probability of 0 and the largest to a probability of 1.

**Usage**

```

quantile(x, ...)

## Default S3 method:
quantile(x, probs = seq(0, 1, 0.25), na.rm = FALSE,
         names = TRUE, type = 7, ...)

```

**Arguments**

|                    |                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | numeric vector whose sample quantiles are wanted, or an object of a class for which a method has been defined (see also ‘details’). <code>NA</code> and <code>NaN</code> values are not allowed in numeric vectors unless <code>na.rm</code> is <code>TRUE</code> . |
| <code>probs</code> | numeric vector of probabilities with values in $[0, 1]$ . (Values up to ‘2e-14’ outside that range are accepted and moved to the nearby endpoint.)                                                                                                                  |
| <code>na.rm</code> | logical; if true, any <code>NA</code> and <code>NaN</code> ’s are removed from <code>x</code> before the quantiles are computed.                                                                                                                                    |
| <code>names</code> | logical; if true, the result has a <code>names</code> attribute. Set to <code>FALSE</code> for speedup with many <code>probs</code> .                                                                                                                               |
| <code>type</code>  | an integer between 1 and 9 selecting one of the nine quantile algorithms detailed below to be used.                                                                                                                                                                 |
| <code>...</code>   | further arguments passed to or from other methods.                                                                                                                                                                                                                  |

**Details**

A vector of length `length(probs)` is returned; if `names = TRUE`, it has a `names` attribute.

`NA` and `NaN` values in `probs` are propagated to the result.

The default method works with classed objects sufficiently like numeric vectors that `sort` and (not needed by types 1 and 3) addition of elements and multiplication by a number work correctly. Note that as this is in a namespace, the copy of `sort` in **base** will be used, not some S4 generic of that

name. Also note that that is no check on the ‘correctly’, and so e.g. quantile can be applied to complex vectors which (apart from ties) will be ordered on their real parts.

There is a method for the date-time classes (see "[POSIXt](#)"). Types 1 and 3 can be used for class "[Date](#)" and for ordered factors.

## Types

quantile returns estimates of underlying distribution quantiles based on one or two order statistics from the supplied elements in  $x$  at probabilities in probs. One of the nine quantile algorithms discussed in Hyndman and Fan (1996), selected by type, is employed.

All sample quantiles are defined as weighted averages of consecutive order statistics. Sample quantiles of type  $i$  are defined by:

$$Q_i(p) = (1 - \gamma)x_j + \gamma x_{j+1}$$

where  $1 \leq i \leq 9$ ,  $\frac{j-m}{n} \leq p < \frac{j-m+1}{n}$ ,  $x_j$  is the  $j$ th order statistic,  $n$  is the sample size, the value of  $\gamma$  is a function of  $j = \lfloor np + m \rfloor$  and  $g = np + m - j$ , and  $m$  is a constant determined by the sample quantile type.

### Discontinuous sample quantile types 1, 2, and 3

For types 1, 2 and 3,  $Q_i(p)$  is a discontinuous function of  $p$ , with  $m = 0$  when  $i = 1$  and  $i = 2$ , and  $m = -1/2$  when  $i = 3$ .

**Type 1** Inverse of empirical distribution function.  $\gamma = 0$  if  $g = 0$ , and 1 otherwise.

**Type 2** Similar to type 1 but with averaging at discontinuities.  $\gamma = 0.5$  if  $g = 0$ , and 1 otherwise.

**Type 3** SAS definition: nearest even order statistic.  $\gamma = 0$  if  $g = 0$  and  $j$  is even, and 1 otherwise.

### Continuous sample quantile types 4 through 9

For types 4 through 9,  $Q_i(p)$  is a continuous function of  $p$ , with  $\gamma = g$  and  $m$  given below. The sample quantiles can be obtained equivalently by linear interpolation between the points  $(p_k, x_k)$  where  $x_k$  is the  $k$ th order statistic. Specific expressions for  $p_k$  are given below.

**Type 4**  $m = 0$ .  $p_k = \frac{k}{n}$ . That is, linear interpolation of the empirical cdf.

**Type 5**  $m = 1/2$ .  $p_k = \frac{k-0.5}{n}$ . That is a piecewise linear function where the knots are the values midway through the steps of the empirical cdf. This is popular amongst hydrologists.

**Type 6**  $m = p$ .  $p_k = \frac{k}{n+1}$ . Thus  $p_k = E[F(x_k)]$ . This is used by Minitab and by SPSS.

**Type 7**  $m = 1 - p$ .  $p_k = \frac{k-1}{n-1}$ . In this case,  $p_k = \text{mode}[F(x_k)]$ . This is used by S.

**Type 8**  $m = (p + 1)/3$ .  $p_k = \frac{k-1/3}{n+1/3}$ . Then  $p_k \approx \text{median}[F(x_k)]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ .

**Type 9**  $m = p/4 + 3/8$ .  $p_k = \frac{k-3/8}{n+1/4}$ . The resulting quantile estimates are approximately unbiased for the expected order statistics if  $x$  is normally distributed.

Further details are provided in Hyndman and Fan (1996) who recommended type 8. The default method is type 7, as used by S and by R < 2.0.0.

r2dtable

*Random 2-way Tables with Given Marginals*

---

## Description

Generate random 2-way tables with given marginals using Patefield's algorithm.

## Usage

```
r2dtable(n, r, c)
```

## Arguments

|   |                                                                                                                        |
|---|------------------------------------------------------------------------------------------------------------------------|
| n | a non-negative numeric giving the number of tables to be drawn.                                                        |
| r | a non-negative vector of length at least 2 giving the row totals, to be coerced to integer. Must sum to the same as c. |
| c | a non-negative vector of length at least 2 giving the column totals, to be coerced to integer.                         |

## Value

A list of length n containing the generated tables as its components.

## References

Patefield, W. M. (1981) Algorithm AS159. An efficient method of generating  $r \times c$  tables with given row and column totals. *Applied Statistics* **30**, 91–97.

## Examples

```
## Fisher's Tea Drinker data.
TeaTasting <-
matrix(c(3, 1, 1, 3),
      nrow = 2,
      dimnames = list(Guess = c("Milk", "Tea"),
                      Truth = c("Milk", "Tea")))
## Simulate permutation test for independence based on the maximum
## Pearson residuals (rather than their sum).
rowTotals <- rowSums(TeaTasting)
colTotals <- colSums(TeaTasting)
nOfCases <- sum(rowTotals)
expected <- outer(rowTotals, colTotals, "*") / nOfCases
maxSqResid <- function(x) max((x - expected) ^ 2 / expected)
simMaxSqResid <-
  sapply(r2dtable(1000, rowTotals, colTotals), maxSqResid)
sum(simMaxSqResid >= maxSqResid(TeaTasting)) / 1000
## Fisher's exact test gives p = 0.4857 ...
```

---

read.ftable

---

*Manipulate Flat Contingency Tables*

---

## Description

Read, write and coerce ‘flat’ contingency tables.

## Usage

```
read.ftable(file, sep = "", quote = "\"",
            row.var.names, col.vars, skip = 0)

write.ftable(x, file = "", quote = TRUE, append = FALSE,
            digits = getOption("digits"), ...)

## S3 method for class 'ftable'
format(x, quote = TRUE, digits = getOption("digits"),
      method = c("non.compact", "row.compact",
                  "col.compact", "compact"),
      lsep = " | ", ...)

## S3 method for class 'ftable'
print(x, digits = getOption("digits"), ...)
```

**Arguments**

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file          | either a character string naming a file or a connection which the data are to be read from or written to. "" indicates input from the console for reading and output to the console for writing.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| sep           | the field separator string. Values on each line of the file are separated by this string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| quote         | a character string giving the set of quoting characters for read.ftable; to disable quoting altogether, use quote="". For write.table, a logical indicating whether strings in the data will be surrounded by double quotes.                                                                                                                                                                                                                                                                                                                                                                                                     |
| row.var.names | a character vector with the names of the row variables, in case these cannot be determined automatically.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| col.vars      | a list giving the names and levels of the column variables, in case these cannot be determined automatically.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| skip          | the number of lines of the data file to skip before beginning to read data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| x             | an object of class "ftable".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| append        | logical. If TRUE and file is the name of a file (and not a connection or " cmd"), the output from write.ftable is appended to the file. If FALSE, the contents of file will be overwritten.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| digits        | an integer giving the number of significant digits to use for (the cell entries of) x.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| method        | string specifying how the "ftable" object is formatted (and printed if used as in write.ftable() or the print method). Can be abbreviated. Available methods are (see the examples):<br><b>"non.compact"</b> the default representation of an "ftable" object.<br><b>"row.compact"</b> a row-compact version without empty cells below the column labels.<br><b>"col.compact"</b> a column-compact version without empty cells to the right of the row labels.<br><b>"compact"</b> a row- and column-compact version. This may imply a row and a column label sharing the same cell. They are then separated by the string lsep. |
| lsep          | only for method = "compact", the separation string for row and column labels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ...           | further arguments to be passed to or from methods; for write() and print(), notably arguments such as method, passed to format().                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Details**

read.ftable reads in a flat-like contingency table from a file. If the file contains the written representation of a flat table (more precisely, a header with all information on names and levels of column variables, followed by a line with the names of the row variables), no further arguments are needed. Similarly, flat tables with only one column variable the name of which is the only entry in the first line are handled automatically. Other variants can be dealt with by skipping all header information using skip, and providing the names of the row variables and the names and levels of the column variable using row.var.names and col.vars, respectively. See the examples below.

Note that flat tables are characterized by their ‘ragged’ display of row (and maybe also column) labels. If the full grid of levels of the row variables is given, one should instead use `read.table` to read in the data, and create the contingency table from this using `xtabs`.

`write.ftable` writes a flat table to a file, which is useful for generating ‘pretty’ ASCII representations of contingency tables. Different versions are available via the `method` argument, which may be useful, for example, for constructing LaTeX tables.

## See Also

`ftable` for more information on flat contingency tables.

## Examples

```
## Agresti (1990), page 157, Table 5.8.
## Not in ftable standard format, but o.k.
file <- tempfile()
cat("          Intercourse\n",
    "Race Gender   Yes  No\n",
    "White Male     43 134\n",
    "      Female    26 149\n",
    "Black Male      29  23\n",
    "      Female     22  36\n",
    file = file)
file.show(file)
ft1 <- read.ftable(file)
ft1
unlink(file)

## Agresti (1990), page 297, Table 8.16.
## Almost o.k., but misses the name of the row variable.
file <- tempfile()
cat("          \"Tonsil Size\"\n",
    "          \"Not Enl.\" \"Enl.\" \"Greatly Enl.\"\n",
    "Noncarriers    497    560        269\n",
    "Carriers       19     29         24\n",
    file = file)
file.show(file)
ft <- read.ftable(file, skip = 2,
                  row.var.names = "Status",
                  col.vars = list("Tonsil Size" =
                                c("Not Enl.", "Enl.", "Greatly Enl.")))
ft
unlink(file)

ft22 <- ftable(Titanic, row.vars = 2:1, col.vars = 4:3)
write.ftable(ft22, quote = FALSE)
write.ftable(ft22, quote = FALSE, method="row.compact")
write.ftable(ft22, quote = FALSE, method="col.compact")
```

```
write.ftable(ft22, quote = FALSE, method="compact")
```

rect.hclust

*Draw Rectangles Around Hierarchical Clusters***Description**

Draws rectangles around the branches of a dendrogram highlighting the corresponding clusters. First the dendrogram is cut at a certain level, then a rectangle is drawn around selected branches.

**Usage**

```
rect.hclust(tree, k = NULL, which = NULL, x = NULL, h = NULL,
            border = 2, cluster = NULL)
```

**Arguments**

|          |                                                                                                                                                                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tree     | an object of the type produced by hclust.                                                                                                                                                                                                 |
| k, h     | Scalar. Cut the dendrogram such that either exactly k clusters are produced or by cutting at height h.                                                                                                                                    |
| which, x | A vector selecting the clusters around which a rectangle should be drawn. which selects clusters by number (from left to right in the tree), x selects clusters containing the respective horizontal coordinates. Default is which = 1:k. |
| border   | Vector with border colors for the rectangles.                                                                                                                                                                                             |
| cluster  | Optional vector with cluster memberships as returned by cutree(hclust.obj, k = k), can be specified for efficiency if already computed.                                                                                                   |

**Value**

(Invisibly) returns a list where each element contains a vector of data points contained in the respective cluster.

**See Also**

[hclust](#), [identify.hclust](#).

**Examples**

```
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
rect.hclust(hca, k = 3, border = "red")
x <- rect.hclust(hca, h = 50, which = c(2,7), border = 3:4)
x
```

|         |                                 |
|---------|---------------------------------|
| relevel | <i>Reorder Levels of Factor</i> |
|---------|---------------------------------|

---

**Description**

The levels of a factor are re-ordered so that the level specified by `ref` is first and the others are moved down. This is useful for `contr.treatment` contrasts which take the first level as the reference.

**Usage**

```
relevel(x, ref, ...)
```

**Arguments**

|                  |                                          |
|------------------|------------------------------------------|
| <code>x</code>   | An unordered factor.                     |
| <code>ref</code> | The reference level.                     |
| <code>...</code> | Additional arguments for future methods. |

**Value**

A factor of the same length as `x`.

**See Also**

[factor](#), [contr.treatment](#), [levels](#), [reorder](#).

**Examples**

```
warpbreaks$tension <- relevel(warpbreaks$tension, ref = "M")
summary(lm(breaks ~ wool + tension, data = warpbreaks))
```

---

|                 |                                   |
|-----------------|-----------------------------------|
| reorder.default | <i>Reorder Levels of a Factor</i> |
|-----------------|-----------------------------------|

---

**Description**

`reorder` is a generic function. The "default" method treats its first argument as a categorical variable, and reorders its levels based on the values of a second variable, usually numeric.

**Usage**

```
reorder(x, ...)

## Default S3 method:
reorder(x, X, FUN = mean, ...,
        order = is.ordered(x))
```

**Arguments**

|                    |                                                                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | An atomic vector, usually a factor (possibly ordered). The vector is treated as a categorical variable whose levels will be reordered. If <code>x</code> is not a factor, its unique values will be used as the implicit levels. |
| <code>X</code>     | a vector of the same length as <code>x</code> , whose subset of values for each unique level of <code>x</code> determines the eventual order of that level.                                                                      |
| <code>FUN</code>   | a function whose first argument is a vector and returns a scalar, to be applied to each subset of <code>X</code> determined by the levels of <code>x</code> .                                                                    |
| <code>...</code>   | optional: extra arguments supplied to <code>FUN</code>                                                                                                                                                                           |
| <code>order</code> | logical, whether return value will be an ordered factor rather than a factor.                                                                                                                                                    |

**Value**

A factor or an ordered factor (depending on the value of `order`), with the order of the levels determined by `FUN` applied to `X` grouped by `x`. The levels are ordered such that the values returned by `FUN` are in increasing order. Empty levels will be dropped.

Additionally, the values of `FUN` applied to the subsets of `X` (in the original order of the levels of `x`) is returned as the "scores" attribute.

**Examples**

```
require(graphics)

bymedian <- with(InsectSprays, reorder(spray, count, median))
boxplot(count ~ bymedian, data = InsectSprays,
        xlab = "Type of spray", ylab = "Insect count",
        main = "InsectSprays data", varwidth = TRUE,
        col = "lightgray")
```

---

`reorder.dendrogram`      *Reorder a Dendrogram*

---

**Description**

A method for the generic function [reorder](#).

There are many different orderings of a dendrogram that are consistent with the structure imposed. This function takes a dendrogram and a vector of values and reorders the dendrogram in the order of the supplied vector, maintaining the constraints on the dendrogram.

**Usage**

```
## S3 method for class 'dendrogram'
reorder(x, wts, agglo.FUN = sum, ...)
```

**Arguments**

|                        |                                                    |
|------------------------|----------------------------------------------------|
| <code>x</code>         | the (dendrogram) object to be reordered            |
| <code>wts</code>       | numeric weights (arbitrary values) for reordering. |
| <code>agglo.FUN</code> | a function for weights agglomeration, see below.   |
| <code>...</code>       | additional arguments                               |

**Details**

Using the weights `wts`, the leaves of the dendrogram are reordered so as to be in an order as consistent as possible with the weights. At each node, the branches are ordered in increasing weights where the weight of a branch is defined as  $f(w_j)$  where  $f$  is `agglo.FUN` and  $w_j$  is the weight of the  $j$ -th sub branch).

**Value**

A dendrogram where each node has a further attribute value with its corresponding weight.

**Author(s)**

R. Gentleman and M. Maechler

**See Also**

[reorder](#).

[rev.dendrogram](#) which simply reverses the nodes' order; [heatmap](#), [cophenetic](#).

**Examples**

```
require(graphics)

set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
dd <- as.dendrogram(hc)
dd.reorder <- reorder(dd, 10:1)
plot(dd, main = "random dendrogram 'dd'")

op <- par(mfcol = 1:2)
plot(dd.reorder, main = "reorder(dd, 10:1)")
plot(reorder(dd, 10:1, agglo.FUN = mean), main = "reorder(dd, 10:1, mean)")
par(op)
```

---

|              |                                        |
|--------------|----------------------------------------|
| replications | <i>Number of Replications of Terms</i> |
|--------------|----------------------------------------|

---

**Description**

Returns a vector or a list of the number of replicates for each term in the formula.

**Usage**

```
replications(formula, data = NULL, na.action)
```

**Arguments**

|           |                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula or a terms object or a data frame.                                                                                                            |
| data      | a data frame used to find the objects in formula.                                                                                                       |
| na.action | function for handling missing values. Defaults to a na.action attribute of data, then a setting of the option na.action, or na.fail if that is not set. |

**Details**

If formula is a data frame and data is missing, formula is used for data with the formula ~ ..

Any character vectors in the formula are coerced to factors.

**Value**

A vector or list with one entry for each term in the formula giving the number(s) of replications for each level. If all levels are balanced (have the same number of replications) the result is a vector, otherwise it is a list with a component for each terms, as a vector, matrix or array as required.

A test for balance is `!is.list(replications(formula,data))`.

**Author(s)**

The design was inspired by the S function of the same name described in Chambers *et al* (1992).

|---------|-----------------------------|
| reshape | <i>Reshape Grouped Data</i> |
|---------|-----------------------------|

---

Description

This function reshapes a data frame between ‘wide’ format with repeated measurements in separate columns of the same record and ‘long’ format with the repeated measurements in separate records.

Usage

```
reshape(data, varying = NULL, v.names = NULL, timevar = "time",
        idvar = "id", ids = 1:NROW(data),
        times = seq_along(varying[[1]]),
        drop = NULL, direction, new.row.names = NULL,
        sep = ".",
        split = if (sep == "") {
          list(regex = "[A-Za-z][0-9]", include = TRUE)
        } else {
          list(regex = sep, include = FALSE, fixed = TRUE)}
)
```

Arguments

|         |                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data    | a data frame                                                                                                                                                                                                                                                                                                                                                                                           |
| varying | names of sets of variables in the wide format that correspond to single variables in long format (‘time-varying’). This is canonically a list of vectors of variable names, but it can optionally be a matrix of names, or a single vector of names. In each case, the names can be replaced by indices which are interpreted as referring to names(data). See ‘Details’ for more details and options. |
| v.names | names of variables in the long format that correspond to multiple variables in the wide format. See ‘Details’.                                                                                                                                                                                                                                                                                         |
| timevar | the variable in long format that differentiates multiple records from the same group or individual. If more than one record matches, the first will be taken (with a warning).                                                                                                                                                                                                                         |

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>idvar</code>         | Names of one or more variables in long format that identify multiple records from the same group/individual. These variables may also be present in wide format.                                                                                                                                                                                                                                                                |
| <code>ids</code>           | the values to use for a newly created <code>idvar</code> variable in long format.                                                                                                                                                                                                                                                                                                                                               |
| <code>times</code>         | the values to use for a newly created <code>timevar</code> variable in long format. See ‘Details’.                                                                                                                                                                                                                                                                                                                              |
| <code>drop</code>          | a vector of names of variables to drop before reshaping.                                                                                                                                                                                                                                                                                                                                                                        |
| <code>direction</code>     | character string, partially matched to either "wide" to reshape to wide format, or "long" to reshape to long format.                                                                                                                                                                                                                                                                                                            |
| <code>new.row.names</code> | character or NULL: a non-null value will be used for the row names of the result.                                                                                                                                                                                                                                                                                                                                               |
| <code>sep</code>           | A character vector of length 1, indicating a separating character in the variable names in the wide format. This is used for guessing <code>v.names</code> and <code>times</code> arguments based on the names in <code>varying</code> . If <code>sep == ""</code> , the split is just before the first numeral that follows an alphabetic character. This is also used to create variable names when reshaping to wide format. |
| <code>split</code>         | A list with three components, <code>regexp</code> , <code>include</code> , and (optionally) <code>fixed</code> . This allows an extended interface to variable name splitting. See ‘Details’.                                                                                                                                                                                                                                   |

## Details

The arguments to this function are described in terms of longitudinal data, as that is the application motivating the functions. A ‘wide’ longitudinal dataset will have one record for each individual with some time-constant variables that occupy single columns and some time-varying variables that occupy a column for each time point. In ‘long’ format there will be multiple records for each individual, with some variables being constant across these records and others varying across the records. A ‘long’ format dataset also needs a ‘time’ variable identifying which time point each record comes from and an ‘id’ variable showing which records refer to the same person.

If the data frame resulted from a previous reshape then the operation can be reversed simply by `reshape(a)`. The `direction` argument is optional and the other arguments are stored as attributes on the data frame.

If `direction = "wide"` and no `varying` or `v.names` arguments are supplied it is assumed that all variables except `idvar` and `timevar` are time-varying. They are all expanded into multiple variables in wide format.

If `direction = "long"` the `varying` argument can be a vector of column names (or a corresponding index). The function will attempt to guess the `v.names` and `times` from these names. The default is variable names like `x.1`, `x.2`, where `sep = "."` specifies to split at the dot and drop it from the name. To have alphabetic followed by numeric times use `sep = ""`.

Variable name splitting as described above is only attempted in the case where `varying` is an atomic vector, if it is a list or a matrix, `v.names` and `times` will generally need to be specified, although they will default to, respectively, the first variable name in each set, and sequential times.

Also, guessing is not attempted if `v.names` is given explicitly. Notice that the order of variables in `varying` is like `x.1,y.1,x.2,y.2`.

The `split` argument should not usually be necessary. The `split$regexp` component is passed to either `strsplit` or `regexpr`, where the latter is used if `split$include` is `TRUE`, in which case the splitting occurs after the first character of the matched string. In the `strsplit` case, the separator is not included in the result, and it is possible to specify fixed-string matching using `split$fixed`.

**Value**

The reshaped data frame with added attributes to simplify reshaping back to the original form.

**Examples**

```
summary(Indometh)
wide <- reshape(Indometh, v.names = "conc", idvar = "Subject",
               timevar = "time", direction = "wide")
wide

reshape(wide, direction = "long")
reshape(wide, idvar = "Subject", varying = list(2:12),
       v.names = "conc", direction = "long")

## times need not be numeric
df <- data.frame(id = rep(1:4, rep(2,4)),
               visit = I(rep(c("Before","After"), 4)),
               x = rnorm(4), y = runif(4))
df
reshape(df, timevar = "visit", idvar = "id", direction = "wide")
## warns that y is really varying
reshape(df, timevar = "visit", idvar = "id", direction = "wide", v.names = "x")

## unbalanced 'long' data leads to NA fill in 'wide' form
df2 <- df[1:7, ]
df2
reshape(df2, timevar = "visit", idvar = "id", direction = "wide")

## Alternative regular expressions for guessing names
df3 <- data.frame(id = 1:4, age = c(40,50,60,50), dose1 = c(1,2,1,2),
               dose2 = c(2,1,2,1), dose4 = c(3,3,3,3))
reshape(df3, direction = "long", varying = 3:5, sep = "")

## an example that isn't longitudinal data
state.x77 <- as.data.frame(state.x77)
long <- reshape(state.x77, idvar = "state", ids = row.names(state.x77),
               times = names(state.x77), timevar = "Characteristic",
               varying = list(names(state.x77)), direction = "long")

reshape(long, direction = "wide")

reshape(long, direction = "wide", new.row.names = unique(long$state))

## multiple id variables
df3 <- data.frame(school = rep(1:3, each = 4), class = rep(9:10, 6),
               time = rep(c(1,1,2,2), 3), score = rnorm(12))
```

```
wide <- reshape(df3, idvar = c("school","class"), direction = "wide")
wide
## transform back
reshape(wide)
```

---

**residuals***Extract Model Residuals*

---

**Description**

`residuals` is a generic function which extracts model residuals from objects returned by modeling functions.

The abbreviated form `resid` is an alias for `residuals`. It is intended to encourage users to access object components through an accessor function rather than by directly referencing an object slot.

All object classes which are returned by model fitting functions should provide a `residuals` method. (Note that the method is for ‘`residuals`’ and not ‘`resid`’.)

Methods can make use of [naresid](#) methods to compensate for the omission of missing values. The default, [nls](#) and [smooth.spline](#) methods do.

**Usage**

```
residuals(object, ...)  
resid(object, ...)
```

**Arguments**

|                     |                                                                      |
|---------------------|----------------------------------------------------------------------|
| <code>object</code> | an object for which the extraction of model residuals is meaningful. |
| <code>...</code>    | other arguments.                                                     |

**Value**

Residuals extracted from the object `object`.

runmed

*Running Medians – Robust Scatter Plot Smoothing***Description**

Compute running medians of odd span. This is the ‘most robust’ scatter plot smoothing possible. For efficiency (and historical reason), you can use one of two different algorithms giving identical results.

**Usage**

```
runmed(x, k, endrule = c("median", "keep", "constant"),
       algorithm = NULL, print.level = 0)
```

**Arguments**

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | numeric vector, the ‘dependent’ variable to be smoothed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| k           | integer width of median window; must be odd. Turlach had a default of $k \leftarrow 1 + 2 * \min((n-1) \% 2, \text{ceiling}(0.1*n))$ . Use $k = 3$ for ‘minimal’ robust smoothing eliminating isolated outliers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| endrule     | character string indicating how the values at the beginning and the end (of the data) should be treated. Can be abbreviated. Possible values are:<br>“keep” keeps the first and last $k_2$ values at both ends, where $k_2$ is the half-bandwidth $k_2 = k \% 2$ , i.e., $y[j] = x[j]$ for $j \in \{1, \dots, k_2; n - k_2 + 1, \dots, n\}$ ;<br>“constant” copies $\text{median}(y[1:k_2])$ to the first values and analogously for the last ones making the smoothed ends <i>constant</i> ;<br>“median” the default, smooths the ends by using symmetrical medians of subsequently smaller bandwidth, but for the very first and last value where Tukey’s robust end-point rule is applied, see <a href="#">smoothEnds</a> . |
| algorithm   | character string (partially matching “Turlach” or “Stuetzle”) or the default NULL, specifying which algorithm should be applied. The default choice depends on $n = \text{length}(x)$ and $k$ where “Turlach” will be used for larger problems.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| print.level | integer, indicating verbosity of algorithm; should rarely be changed by average users.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Details**

Apart from the end values, the result  $y = \text{runmed}(x, k)$  simply has  $y[j] = \text{median}(x[(j-k_2):(j+k_2)])$  ( $k = 2*k_2+1$ ), computed very efficiently.

The two algorithms are internally entirely different:

“Turlach” is the Härdle–Steiger algorithm (see Ref.) as implemented by Berwin Turlach. A tree algorithm is used, ensuring performance  $O(n \log k)$  where  $n = \text{length}(x)$  which is asymptotically optimal.

"Stuetzle" is the (older) Stuetzle–Friedman implementation which makes use of median *updating* when one observation enters and one leaves the smoothing window. While this performs as  $O(n \times k)$  which is slower asymptotically, it is considerably faster for small  $k$  or  $n$ .

Currently long vectors are only supported for `algorithm = "Stuetzle"`.

### Value

vector of smoothed values of the same length as `x` with an `attribute` `k` containing (the 'oddified') `k`.

### Author(s)

Martin Maechler <maechler@stat.math.ethz.ch>, based on Fortran code from Werner Stuetzle and S-PLUS and C code from Berwin Turlach.

```

rWishart

*Random Wishart Distributed Matrices***Description**

Generate  $n$  random matrices, distributed according to the Wishart distribution with parameters Sigma and df,  $W_p(\Sigma, m)$ ,  $m = \text{df}$ ,  $\Sigma = \text{Sigma}$ .

**Usage**

```
rWishart(n, df, Sigma)
```

**Arguments**

|       |                                                                                              |
|-------|----------------------------------------------------------------------------------------------|
| n     | integer sample size.                                                                         |
| df    | numeric parameter, “degrees of freedom”.                                                     |
| Sigma | positive definite ( $p \times p$ ) “scale” matrix, the matrix parameter of the distribution. |

**Details**

If  $X_1, \dots, X_m$ ,  $X_i \in \mathbf{R}^p$  is a sample of  $m$  independent multivariate Gaussians with mean (vector) 0, and covariance matrix  $\Sigma$ , the distribution of  $M = X'X$  is  $W_p(\Sigma, m)$ .

Consequently, the expectation of  $M$  is

$$E[M] = m \times \Sigma.$$

Further, if Sigma is scalar ( $p = 1$ ), the Wishart distribution is a scaled chi-squared ( $\chi^2$ ) distribution with df degrees of freedom,  $W_1(\sigma^2, m) = \sigma^2 \chi_m^2$ .

The component wise variance is

$$\text{Var}(M_{ij}) = m(\Sigma_{ij}^2 + \Sigma_{ii}\Sigma_{jj}).$$

**Value**

a numeric [array](#), say  $R$ , of dimension  $p \times p \times n$ , where each  $R[, , i]$  is a positive definite matrix, a realization of the Wishart distribution  $W_p(\Sigma, m)$ ,  $m = \text{df}$ ,  $\Sigma = \text{Sigma}$ .

scatter.smooth

---

*Scatter Plot with Smooth Curve Fitted by Loess*

---

**Description**

Plot and add a smooth curve computed by loess to a scatter plot.

**Usage**

```
scatter.smooth(x, y = NULL, span = 2/3, degree = 1,
  family = c("symmetric", "gaussian"),
  xlab = NULL, ylab = NULL,
  ylim = range(y, pred$y, na.rm = TRUE),
  evaluation = 50, ..., lpars = list())

loess.smooth(x, y, span = 2/3, degree = 1,
  family = c("symmetric", "gaussian"), evaluation = 50, ...)
```

### Arguments

|                         |                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>       | the <code>x</code> and <code>y</code> arguments provide the <code>x</code> and <code>y</code> coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function <a href="#">xy.coords</a> for details. |
| <code>span</code>       | smoothness parameter for loess.                                                                                                                                                                                                               |
| <code>degree</code>     | degree of local polynomial used.                                                                                                                                                                                                              |
| <code>family</code>     | if "gaussian" fitting is by least-squares, and if <code>family = "symmetric"</code> a re-descending M estimator is used. Can be abbreviated.                                                                                                  |
| <code>xlab</code>       | label for <code>x</code> axis.                                                                                                                                                                                                                |
| <code>ylab</code>       | label for <code>y</code> axis.                                                                                                                                                                                                                |
| <code>ylim</code>       | the <code>y</code> limits of the plot.                                                                                                                                                                                                        |
| <code>evaluation</code> | number of points at which to evaluate the smooth curve.                                                                                                                                                                                       |
| <code>...</code>        | For <code>scatter.smooth()</code> , graphical parameters, passed to <code>plot()</code> only. For <code>loess.smooth</code> , control parameters passed to <a href="#">loess.control</a> .                                                    |
| <code>lpars</code>      | a <a href="#">list</a> of arguments to be passed to <a href="#">lines()</a> .                                                                                                                                                                 |

### Details

`loess.smooth` is an auxiliary function which evaluates the loess smooth at evaluation equally spaced points covering the range of `x`.

### Value

For `scatter.smooth`, none.

For `loess.smooth`, a list with two components, `x` (the grid of evaluation points) and `y` (the smoothed values at the grid points).

### See Also

[loess](#); [smoothScatter](#) for scatter plots with smoothed *density* color representation.

### Examples

```
require(graphics)

with(cars, scatter.smooth(speed, dist))
## or with dotted thick smoothed line results :
with(cars, scatter.smooth(speed, dist, lpars =
  list(col = "red", lwd = 3, lty = 3)))
```

screepLOT

*ScreepLOTS*

## Description

screepLOT.default plots the variances against the number of the principal component. This is also the plot method for classes "princomp" and "prcomp".

## Usage

```
## Default S3 method:
screepLOT(x, npcs = min(10, length(x$sdev)),
          type = c("barplot", "lines"),
          main = deparse(substitute(x)), ...)
```

## Arguments

|           |                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------|
| x         | an object containing a sdev component, such as that returned by <a href="#">princomp()</a> and <a href="#">prcomp()</a> . |
| npcs      | the number of components to be plotted.                                                                                   |
| type      | the type of plot. Can be abbreviated.                                                                                     |
| main, ... | graphics parameters.                                                                                                      |

## Examples

```
require(graphics)

## The variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests, cor = TRUE)) # inappropriate
screepLOT(pc.cr)

fit <- princomp(covmat = Harman74.cor)
screepLOT(fit)
screepLOT(fit, npcs = 24, type = "lines")
```

---

|    |                           |
|----|---------------------------|
| sd | <i>Standard Deviation</i> |
|----|---------------------------|

---

**Description**

This function computes the standard deviation of the values in `x`. If `na.rm` is `TRUE` then missing values are removed before computation proceeds.

**Usage**

```
sd(x, na.rm = FALSE)
```

**Arguments**

|                    |                                                                                          |
|--------------------|------------------------------------------------------------------------------------------|
| <code>x</code>     | a numeric vector or an R object which is coercible to one by <code>as.double(x)</code> . |
| <code>na.rm</code> | logical. Should missing values be removed?                                               |

**Details**

Like `var` this uses denominator  $n - 1$ .

The standard deviation of a zero-length vector (after removal of NAs if `na.rm = TRUE`) is not defined and gives an error. The standard deviation of a length-one vector is NA.

**See Also**

`var` for its square, and `mad`, the most robust alternative.

**Examples**

```
sd(1:2) ^ 2
```

---

|             |                                                     |
|-------------|-----------------------------------------------------|
| se.contrast | <i>Standard Errors for Contrasts in Model Terms</i> |
|-------------|-----------------------------------------------------|

---

**Description**

Returns the standard errors for one or more contrasts in an aov object.

**Usage**

```
se.contrast(object, ...)
## S3 method for class 'aov'
se.contrast(object, contrast.obj,
             coef = contr.helmert(ncol(contrast))[, 1],
             data = NULL, ...)
```

**Arguments**

|                           |                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>       | A suitable fit, usually from <code>aov</code> .                                                                                                                                                                                                                                                                                        |
| <code>contrast.obj</code> | The contrasts for which standard errors are requested. This can be specified via a list or via a matrix. A single contrast can be specified by a list of logical vectors giving the cells to be contrasted. Multiple contrasts should be specified by a matrix, each column of which is a numerical contrast vector (summing to zero). |
| <code>coef</code>         | used when <code>contrast.obj</code> is a list; it should be a vector of the same length as the list with zero sum. The default value is the first Helmert contrast, which contrasts the first and second cell means specified by the list.                                                                                             |
| <code>data</code>         | The data frame used to evaluate <code>contrast.obj</code> .                                                                                                                                                                                                                                                                            |
| <code>...</code>          | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                     |

**Details**

Contrasts are usually used to test if certain means are significantly different; it can be easier to use `se.contrast` than compute them directly from the coefficients.

In multistratum models, the contrasts can appear in more than one stratum, in which case the standard errors are computed in the lowest stratum and adjusted for efficiencies and comparisons between strata. (See the comments in the note in the help for [aov](#) about using orthogonal contrasts.) Such standard errors are often conservative.

Suitable matrices for use with `coef` can be found by calling [contrasts](#) and indexing the columns by a factor.

**Value**

A vector giving the standard errors for each contrast.

**See Also**

[contrasts](#), [model.tables](#)

summary(fit2)$tTable # same estimates, similar (but smaller) se's.

```

## Description

Construct self-starting nonlinear models.

**Usage**

```
selfStart(model, initial, parameters, template)
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model</code>      | a function object defining a nonlinear model or a nonlinear formula object of the form <code>~expression</code> .                                                                                                                                                                                                                                                                                                                                           |
| <code>initial</code>    | a function object, taking three arguments: <code>mCall</code> , <code>data</code> , and <code>LHS</code> , representing, respectively, a matched call to the function <code>model</code> , a data frame in which to interpret the variables in <code>mCall</code> , and the expression from the left-hand side of the model formula in the call to <code>nls</code> . This function should return initial values for the parameters in <code>model</code> . |
| <code>parameters</code> | a character vector specifying the terms on the right hand side of <code>model</code> for which initial estimates should be calculated. Passed as the <code>namevec</code> argument to the <code>deriv</code> function.                                                                                                                                                                                                                                      |
| <code>template</code>   | an optional prototype for the calling sequence of the returned object, passed as the <code>function.arg</code> argument to the <code>deriv</code> function. By default, a template is generated with the covariates in <code>model</code> coming first and the parameters in <code>model</code> coming last in the calling sequence.                                                                                                                        |

**Details**

This function is generic; methods functions can be written to handle specific classes of objects.

**Value**

a function object of class "selfStart", for the formula method obtained by applying `deriv` to the right hand side of the model formula. An `initial` attribute (defined by the `initial` argument) is added to the function to calculate starting estimates for the parameters in the model automatically.

**Author(s)**

José Pinheiro and Douglas Bates

**Examples**

```
## self-starting logistic model

SSlogis <- selfStart(~ Asym/(1 + exp((xmid - x)/scal)),
  function(mCall, data, LHS)
  {
    xy <- sortedXyData(mCall[["x"]], LHS, data)
    if(nrow(xy) < 4) {
```

```

    stop("Too few distinct x values to fit a logistic")
  }
  z <- xy[["y"]]
  if (min(z) <= 0) { z <- z + 0.05 * max(z) } # avoid zeroes
  z <- z/(1.05 * max(z)) # scale to within unit height
  xy[["z"]] <- log(z/(1 - z)) # logit transformation
  aux <- coef(lm(x ~ z, xy))
  parameters(xy) <- list(xmid = aux[1], scal = aux[2])
  pars <- as.vector(coef(nls(y ~ 1/(1 + exp((xmid - x)/scal)),
    data = xy, algorithm = "plinear")))
  setNames(c(pars[3], pars[1], pars[2]),
    mCall[c("Asym", "xmid", "scal")])
}, c("Asym", "xmid", "scal"))

# 'first.order.log.model' is a function object defining a first order
# compartment model
# 'first.order.log.initial' is a function object which calculates initial
# values for the parameters in 'first.order.log.model'

# self-starting first order compartment model
## Not run:
SSfol <- selfStart(first.order.log.model, first.order.log.initial)

## End(Not run)

## Explore the self-starting models already available in R's "stats":
pos.st <- which("package:stats" == search())
mSS <- apropos("^SS..", where = TRUE, ignore.case = FALSE)
(mSS <- unname(mSS[names(mSS) == pos.st]))
fSS <- sapply(mSS, get, pos = pos.st, mode = "function")
all(sapply(fSS, inherits, "selfStart")) # -> TRUE

## Show the argument list of each self-starting function:
str(fSS, give.attr = FALSE)

```

---

setNames

---

*Set the Names in an Object*

---

## Description

This is a convenience function that sets the names on an object and returns the object. It is most useful at the end of a function definition where one is creating the object to be returned and would prefer not to store it under a name just so the names can be assigned.

## Usage

```
setNames(object = nm, nm)
```

**Arguments**

|        |                                                          |
|--------|----------------------------------------------------------|
| object | an object for which a names attribute will be meaningful |
| nm     | a character vector of names to assign to the object      |

**Value**

An object of the same sort as object with the new names assigned.

**Author(s)**

Douglas M. Bates and Saikat DebRoy

**See Also**

[unname](#) for removing names.

**Examples**

```
setNames( 1:3, c("foo", "bar", "baz") )
# this is just a short form of
tmp <- 1:3
names(tmp) <- c("foo", "bar", "baz")
tmp

## special case of character vector, using default
setNames(nm = c("First", "2nd"))
```

---

shapiro.test

*Shapiro-Wilk Normality Test*

---

**Description**

Performs the Shapiro-Wilk test of normality.

**Usage**

```
shapiro.test(x)
```

**Arguments**

|   |                                                                                                                               |
|---|-------------------------------------------------------------------------------------------------------------------------------|
| x | a numeric vector of data values. Missing values are allowed, but the number of non-missing values must be between 3 and 5000. |
|---|-------------------------------------------------------------------------------------------------------------------------------|

**Value**

A list with class "htest" containing the following components:

|           |                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------|
| statistic | the value of the Shapiro-Wilk statistic.                                                                 |
| p.value   | an approximate p-value for the test. This is said in Royston (1995) to be adequate for $p.value < 0.1$ . |
| method    | the character string "Shapiro-Wilk normality test".                                                      |
| data.name | a character string giving the name(s) of the data.                                                       |

**Source**

The algorithm used is a C translation of the Fortran code described in Royston (1995) and found at <http://lib.stat.cmu.edu/apstat/R94>. The calculation of the p value is exact for  $n = 3$ , otherwise approximations are used, separately for  $4 \leq n \leq 11$  and  $n \geq 12$ .

**See Also**

[qqnorm](#) for producing a normal quantile-quantile plot.

**Examples**

```
shapiro.test(rnorm(100, mean = 5, sd = 3))
shapiro.test(runif(100, min = 2, max = 4))
```

---

SignRank

---

*Distribution of the Wilcoxon Signed Rank Statistic*

---

**Description**

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon Signed Rank statistic obtained from a sample with size  $n$ .

**Usage**

```
dsignrank(x, n, log = FALSE)
psignrank(q, n, lower.tail = TRUE, log.p = FALSE)
qsignrank(p, n, lower.tail = TRUE, log.p = FALSE)
rsignrank(nn, n)
```

**Arguments**

|                                       |                                                                                                            |
|---------------------------------------|------------------------------------------------------------------------------------------------------------|
| <code>x</code> , <code>q</code>       | vector of quantiles.                                                                                       |
| <code>p</code>                        | vector of probabilities.                                                                                   |
| <code>nn</code>                       | number of observations. If <code>length(nn) &gt; 1</code> , the length is taken to be the number required. |
| <code>n</code>                        | number(s) of observations in the sample(s). A positive integer, or a vector of such integers.              |
| <code>log</code> , <code>log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$ .                                    |
| <code>lower.tail</code>               | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                      |

**Details**

This distribution is obtained as follows. Let  $x$  be a sample of size  $n$  from a continuous distribution symmetric about the origin. Then the Wilcoxon signed rank statistic is the sum of the ranks of the absolute values  $x[i]$  for which  $x[i]$  is positive. This statistic takes values between 0 and  $n(n+1)/2$ , and its mean and variance are  $n(n+1)/4$  and  $n(n+1)(2n+1)/24$ , respectively.

If either of the first two arguments is a vector, the recycling rule is used to do the calculations for all combinations of the two up to the length of the longer vector.

**Value**

`dsignrank` gives the density, `psignrank` gives the distribution function, `qsignrank` gives the quantile function, and `rsignrank` generates random deviates.

The length of the result is determined by `nn` for `rsignrank`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `nn` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Author(s)**

Kurt Hornik; efficiency improvement by Ivo Ugrina.

**See Also**

|          |                           |
|----------|---------------------------|
| simulate | <i>Simulate Responses</i> |
|----------|---------------------------|

---

**Description**

Simulate one or more responses from the distribution corresponding to a fitted model object.

**Usage**

simulate(object, nsim = 1, seed = NULL, ...)

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object representing a fitted model.                                                                                                                                                                                                                                                                                                                                                                                                |
| nsim   | number of response vectors to simulate. Defaults to 1.                                                                                                                                                                                                                                                                                                                                                                                |
| seed   | an object specifying if and how the random number generator should be initialized ('seeded').<br>For the "lm" method, either NULL or an integer that will be used in a call to set.seed before simulating the response vectors. If set, the value is saved as the "seed" attribute of the returned value. The default, NULL will not change the random generator state, and return .Random.seed as the "seed" attribute, see 'Value'. |
| ...    | additional optional arguments.                                                                                                                                                                                                                                                                                                                                                                                                        |

**Details**

This is a generic function. Consult the individual modeling functions for details on how to use this function.

Package **stats** has a method for "lm" objects which is used for **lm** and **glm** fits. There is a method for fits from glm.nb in package **MASS**, and hence the case of negative binomial families is not covered by the "lm" method.

The methods for linear models fitted by lm or glm(family = "gaussian") assume that any weights which have been supplied are inversely proportional to the error variance. For other GLMs the (optional) simulate component of the family object is used—there is no appropriate simulation method for 'quasi' models as they are specified only up to two moments.

For binomial and Poisson GLMs the dispersion is fixed at one. Integer prior weights  $w_i$  can be interpreted as meaning that observation  $i$  is an average of  $w_i$  observations, which is natural for binomials specified as proportions but less so for a Poisson, for which prior weights are ignored with a warning.

For a gamma GLM the shape parameter is estimated by maximum likelihood (using function **gamma.shape** in package **MASS**). The interpretation of weights is as multipliers to a basic shape parameter, since dispersion is inversely proportional to shape.

For an inverse gaussian GLM the model assumed is  $IG(\mu_i, \lambda w_i)$  (see [https://en.wikipedia.org/wiki/Inverse\\_Gaussian\\_distribution](https://en.wikipedia.org/wiki/Inverse_Gaussian_distribution)) where  $\lambda$  is estimated by the inverse of the dispersion estimate for the fit. The variance is  $\mu_i^3/(\lambda w_i)$  and hence inversely proportional to the prior weights. The simulation is done by function `rinvGauss` from the **SuppDists** package, which must be installed.

## Value

Typically, a list of length `nsim` of simulated responses. Where appropriate the result can be a data frame (which is a special type of list).

For the "lm" method, the result is a data frame with an attribute "seed". If argument `seed` is `NULL`, the attribute is the value of `.Random.seed` before the simulation was started; otherwise it is the value of the argument with a "kind" attribute with value `as.list(RNGkind())`.

## See Also

`RNG` about random number generation in R, `fitted.values` and `residuals` for related methods; `glm`, `lm` for model fitting.

There are further examples in the 'simulate.R' tests file in the sources for package **stats**.

## Examples

```
x <- 1:5
mod1 <- lm(c(1:3, 7, 6) ~ x)
S1 <- simulate(mod1, nsim = 4)
## repeat the simulation:
.Random.seed <- attr(S1, "seed")
identical(S1, simulate(mod1, nsim = 4))

S2 <- simulate(mod1, nsim = 200, seed = 101)
rowMeans(S2) # should be about the same as
fitted(mod1)

## repeat identically:
(sseed <- attr(S2, "seed")) # seed; RNGkind as attribute
stopifnot(identical(S2, simulate(mod1, nsim = 200, seed = sseed)))

## To be sure about the proper RNGkind, e.g., after
RNGversion("2.7.0")
## first set the RNG kind, then simulate
do.call(RNGkind, attr(sseed, "kind"))
identical(S2, simulate(mod1, nsim = 200, seed = sseed))

## Binomial GLM examples
yb1 <- matrix(c(4, 4, 5, 7, 8, 6, 6, 5, 3, 2), ncol = 2)
modb1 <- glm(yb1 ~ x, family = binomial)
S3 <- simulate(modb1, nsim = 4)
# each column of S3 is a two-column matrix.

x2 <- sort(runif(100))
yb2 <- rbinom(100, prob = plogis(2*(x2-1)), size = 1)
```

```

|        |                                           |
|--------|-------------------------------------------|
| smooth | <i>Tukey's (Running Median) Smoothing</i> |
|--------|-------------------------------------------|

---

**Description**

Tukey's smoothers, *3RS3R*, *3RSS*, *3R*, etc.

**Usage**

```
smooth(x, kind = c("3RS3R", "3RSS", "3RSR", "3R", "3", "S"),
       twiceit = FALSE, endrule = "Tukey", do.ends = FALSE)
```

**Arguments**

|         |                                                                                                                                                                                                                 |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x       | a vector or time series                                                                                                                                                                                         |
| kind    | a character string indicating the kind of smoother required; defaults to "3RS3R".                                                                                                                               |
| twiceit | logical, indicating if the result should be 'twiced'. Twicing a smoother $S(y)$ means $S(y) + S(y - S(y))$ , i.e., adding smoothed residuals to the smoothed values. This decreases bias (increasing variance). |
| endrule | a character string indicating the rule for smoothing at the boundary. Either "Tukey" (default) or "copy".                                                                                                       |
| do.ends | logical, indicating if the 3-splitting of ties should also happen at the boundaries (ends). This is only used for kind = "S".                                                                                   |

**Details**

3 is Tukey's short notation for running [medians](#) of length 3,  
3R stands for **R**epeated 3 until convergence, and  
S for **S**plitting of horizontal stretches of length 2 or 3.  
Hence, 3RS3R is a concatenation of 3R, S and 3R, 3RSS similarly, whereas 3RSR means first 3R and then (S and 3) **R**epeated until convergence – which can be bad.

**Value**

An object of class "tukeysmooth" (which has print and summary methods) and is a vector or time series containing the smoothed values with additional attributes.

**Note**

S and S-PLUS use a different (somewhat better) Tukey smoother in `smooth(*)`. Note that there are other smoothing methods which provide rather better results. These were designed for hand calculations and may be used mainly for didactical purposes.

Since R version 1.2, `smooth` *does* really implement Tukey's end-point rule correctly (see argument `endrule`).

`kind = "3RSR"` has been the default till R-1.1, but it can have very bad properties, see the examples.

Note that repeated application of `smooth(*)` *does* smooth more, for the "3RS\*" kinds.

smooth.spline

*Fit a Smoothing Spline*

---

## Description

Fits a cubic smoothing spline to the supplied data.

## Usage

```
smooth.spline(x, y = NULL, w = NULL, df, spar = NULL, cv = FALSE,
              all.knots = FALSE, nknots = .nknots.smspl,
              keep.data = TRUE, df.offset = 0, penalty = 1,
              control.spar = list(), tol = 1e-6 * IQR(x))
```

## Arguments

|           |                                                                                                                                                                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | a vector giving the values of the predictor variable, or a list or a two-column matrix specifying x and y.                                                                                                                                                       |
| y         | responses. If y is missing or NULL, the responses are assumed to be specified by x, with x the index vector.                                                                                                                                                     |
| w         | optional vector of weights of the same length as x; defaults to all 1.                                                                                                                                                                                           |
| df        | the desired equivalent number of degrees of freedom (trace of the smoother matrix).                                                                                                                                                                              |
| spar      | smoothing parameter, typically (but not necessarily) in (0, 1]. The coefficient $\lambda$ of the integral of the squared second derivative in the fit (penalized log likelihood) criterion is a monotone function of spar, see the details below.                |
| cv        | ordinary (TRUE) or ‘generalized’ cross-validation (GCV) when FALSE; setting it to NA skips the evaluation of leverages and any score.                                                                                                                            |
| all.knots | if TRUE, all distinct points in x are used as knots. If FALSE (default), a subset of x[] is used, specifically x[j] where the nknots indices are evenly spaced in 1:n, see also the next argument nknots.                                                        |
| nknots    | integer or <a href="#">function</a> giving the number of knots to use when all.knots = FALSE. If a function (as by default), the number of knots is nknots(nx). By default for $n_x > 49$ this is less than $n_x$ , the number of unique x values, see the Note. |
| keep.data | logical specifying if the input data should be kept in the result. If TRUE (as per default), fitted values and residuals are available from the result.                                                                                                          |
| df.offset | allows the degrees of freedom to be increased by df.offset in the GCV criterion.                                                                                                                                                                                 |
| penalty   | the coefficient of the penalty for degrees of freedom in the GCV criterion.                                                                                                                                                                                      |

- `control.spar` optional list with named components controlling the root finding when the smoothing parameter `spar` is computed, i.e., missing or NULL, see below.
- Note** that this is partly *experimental* and may change with general `spar` computation improvements!
- low:** lower bound for `spar`; defaults to -1.5 (used to implicitly default to 0 in R versions earlier than 1.4).
- high:** upper bound for `spar`; defaults to +1.5.
- tol:** the absolute precision (**tolerance**) used; defaults to 1e-4 (formerly 1e-3).
- eps:** the relative precision used; defaults to 2e-8 (formerly 0.00244).
- trace:** logical indicating if iterations should be traced.
- maxit:** integer giving the maximal number of iterations; defaults to 500.
- Note that `spar` is only searched for in the interval  $[low, high]$ .
- `tol` a tolerance for same-ness or uniqueness of the `x` values. The values are binned into bins of size `tol` and values which fall into the same bin are regarded as the same. Must be strictly positive (and finite).

## Details

Neither `x` nor `y` are allowed to containing missing or infinite values.

The `x` vector should contain at least four distinct values. ‘Distinct’ here is controlled by `tol`: values which are regarded as the same are replaced by the first of their values and the corresponding `y` and `w` are pooled accordingly.

The computational  $\lambda$  used (as a function of  $s = spar$ ) is  $\lambda = r * 256^{3s-1}$  where  $r = tr(X'WX)/tr(\Sigma)$ ,  $\Sigma$  is the matrix given by  $\Sigma_{ij} = \int B_i''(t)B_j''(t)dt$ ,  $X$  is given by  $X_{ij} = B_j(x_i)$ ,  $W$  is the diagonal matrix of weights (scaled such that its trace is  $n$ , the original number of observations) and  $B_k(\cdot)$  is the  $k$ -th B-spline.

Note that with these definitions,  $f_i = f(x_i)$ , and the B-spline basis representation  $f = Xc$  (i.e.,  $c$  is the vector of spline coefficients), the penalized log likelihood is  $L = (y - f)'W(y - f) + \lambda c'\Sigma c$ , and hence  $c$  is the solution of the (ridge regression)  $(X'WX + \lambda\Sigma)c = X'Wy$ .

If `spar` is missing or NULL, the value of `df` is used to determine the degree of smoothing. If both are missing, leave-one-out cross-validation (ordinary or ‘generalized’ as determined by `cv`) is used to determine  $\lambda$ . Note that from the above relation,

`spar` is  $s = s_0 + 0.0601 * \log \lambda$ , which is intentionally *different* from the S-PLUS implementation of `smooth.spline` (where `spar` is proportional to  $\lambda$ ). In R’s ( $\log \lambda$ ) scale, it makes more sense to vary `spar` linearly.

Note however that currently the results may become very unreliable for `spar` values smaller than about -1 or -2. The same may happen for values larger than 2 or so. Don’t think of setting `spar` or the controls `low` and `high` outside such a safe range, unless you know what you are doing!

The ‘generalized’ cross-validation method will work correctly when there are duplicated points in `x`. However, it is ambiguous what leave-one-out cross-validation means with duplicated points, and the internal code uses an approximation that involves leaving out groups of duplicated points. `cv = TRUE` is best avoided in that case.

**Value**

An object of class "smooth.spline" with components

|          |                                                                                                                                                                                                                                                                                                                                                        |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x        | the <i>distinct</i> x values in increasing order, see the ‘Details’ above.                                                                                                                                                                                                                                                                             |
| y        | the fitted values corresponding to x.                                                                                                                                                                                                                                                                                                                  |
| w        | the weights used at the unique values of x.                                                                                                                                                                                                                                                                                                            |
| yin      | the y values used at the unique y values.                                                                                                                                                                                                                                                                                                              |
| data     | only if keep.data = TRUE: itself a <b>list</b> with components x, y and w of the same length. These are the original $(x_i, y_i, w_i), i = 1, \dots, n$ , values where data\$x may have repeated values and hence be longer than the above x component; see details.                                                                                   |
| lev      | (when cv was not NA) leverages, the diagonal values of the smoother matrix.                                                                                                                                                                                                                                                                            |
| cv.crit  | cross-validation score, ‘generalized’ or true, depending on cv.                                                                                                                                                                                                                                                                                        |
| pen.crit | penalized criterion                                                                                                                                                                                                                                                                                                                                    |
| crit     | the criterion value minimized in the underlying .Fortran routine ‘sslvrq’.                                                                                                                                                                                                                                                                             |
| df       | equivalent degrees of freedom used. Note that (currently) this value may become quite imprecise when the true df is between and 1 and 2.                                                                                                                                                                                                               |
| spar     | the value of spar computed or given.                                                                                                                                                                                                                                                                                                                   |
| lambda   | the value of $\lambda$ corresponding to spar, see the details above.                                                                                                                                                                                                                                                                                   |
| iparms   | named integer(3) vector where ..\$ipars["iter"] gives number of spar computing iterations used.                                                                                                                                                                                                                                                        |
| fit      | list for use by <b>predict.smooth.spline</b> , with components<br><b>knot</b> : the knot sequence (including the repeated boundary knots).<br><b>nk</b> : number of coefficients or number of ‘proper’ knots plus 2.<br><b>coef</b> : coefficients for the spline basis used.<br><b>min, range</b> : numbers giving the corresponding quantities of x. |
| call     | the matched call.                                                                                                                                                                                                                                                                                                                                      |

**Note**

The number of unique x values,  $n_x = n_x$ , are determined by the tol argument, equivalently to

```
nx <- length(x) - sum(duplicated( round((x - mean(x)) / tol) ))
```

The default all.knots = FALSE and nknots = .nknots.smspl, entails using only  $O(n_x^{0.2})$  knots instead of  $n_x$  for  $n_x > 49$ . This cuts speed and memory requirements, but not drastically anymore since R version 1.5.1 where it is only  $O(n_k) + O(n)$  where  $n_k$  is the number of knots.

In this case where not all unique x values are used as knots, the result is not a smoothing spline in the strict sense, but very close unless a small smoothing parameter (or large df) is used.

**Author(s)**

R implementation by B. D. Ripley and Martin Maechler (spar/lambda, etc).

## Source

This function is based on code in the GAMFIT Fortran program by T. Hastie and R. Tibshirani (<http://lib.stat.cmu.edu/general/>), which makes use of spline code by Finbarr O'Sullivan. Its design parallels the smooth.spline function of Chambers & Hastie (1992).

## The following shows the problematic behavior of 'spar' searching:
(s2 <- smooth.spline(y18, control =
  list(trace = TRUE, tol = 1e-6, low = -1.5)))
(s2m <- smooth.spline(y18, cv = TRUE, control =
  list(trace = TRUE, tol = 1e-6, low = -1.5)))
## both above do quite similarly (Df = 8.5 +- 0.2)

```

smoothEnds

*End Points Smoothing (for Running Medians)***Description**

Smooth end points of a vector *y* using subsequently smaller medians and Tukey's end point rule at the very end. (of odd span),

**Usage**

```
smoothEnds(y, k = 3)
```

**Arguments**

*y* dependent variable to be smoothed (vector).  
*k* width of largest median window; must be odd.

**Details**

smoothEnds is used to only do the 'end point smoothing', i.e., change at most the observations closer to the beginning/end than half the window *k*. The first and last value are computed using *Tukey's end point rule*, i.e.,  $sm[1] = \text{median}(y[1], sm[2], 3*sm[2] - 2*sm[3])$ .

**Value**

vector of smoothed values, the same length as *y*.

**See Also**

`runmed(*, endrule = "median")` which calls `smoothEnds()`.

**Examples**

```
require(graphics)

y <- ys <- (-20:20)^2
y [c(1,10,21,41)] <- c(100, 30, 400, 470)
s7k <- runmed(y, 7, endrule = "keep")
s7. <- runmed(y, 7, endrule = "const")
s7m <- runmed(y, 7)
col3 <- c("midnightblue", "blue", "steelblue")
plot(y, main = "Running Medians -- runmed(*, k=7, end.rule = X)")
lines(ys, col = "light gray")
matlines(cbind(s7k, s7., s7m), lwd = 1.5, lty = 1, col = col3)
legend(1, 470, paste("endrule", c("keep", "constant", "median"), sep = " = "),
      col = col3, lwd = 1.5, lty = 1)

stopifnot(identical(s7m, smoothEnds(s7k, 7)))
```

---

sortedXyData

---

*Create a sortedXyData Object*

---

**Description**

This is a constructor function for the class of sortedXyData objects. These objects are mostly used in the initial function for a self-starting nonlinear regression model, which will be of the selfStart class.

**Usage**

```
sortedXyData(x, y, data)
```

**Arguments**

|      |                                                                                                       |
|------|-------------------------------------------------------------------------------------------------------|
| x    | a numeric vector or an expression that will evaluate in data to a numeric vector                      |
| y    | a numeric vector or an expression that will evaluate in data to a numeric vector                      |
| data | an optional data frame in which to evaluate expressions for x and y, if they are given as expressions |

**Value**

A sortedXyData object. This is a data frame with exactly two numeric columns, named x and y. The rows are sorted so the x column is in increasing order. Duplicate x values are eliminated by averaging the corresponding y values.

**Author(s)**

José Pinheiro and Douglas Bates

**Examples**

```
DNase.2 <- DNase[ DNase$Run == "2", ]
sortedXyData( expression(log(conc)), expression(density), DNase.2 )
```

---

|         |                                                               |
|---------|---------------------------------------------------------------|
| spec.ar | <i>Estimate Spectral Density of a Time Series from AR Fit</i> |
|---------|---------------------------------------------------------------|

---

**Description**

Fits an AR model to x (or uses the existing fit) and computes (and by default plots) the spectral density of the fitted model.

**Usage**

```
spec.ar(x, n.freq, order = NULL, plot = TRUE, na.action = na.fail,
        method = "yule-walker", ...)
```

**Arguments**

|           |                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------|
| x         | A univariate (not yet:or multivariate) time series or the result of a fit by <a href="#">ar</a> . |
| n.freq    | The number of points at which to plot.                                                            |
| order     | The order of the AR model to be fitted. If omitted, the order is chosen by AIC.                   |
| plot      | Plot the periodogram?                                                                             |
| na.action | NA action function.                                                                               |
| method    | method for <a href="#">ar</a> fit.                                                                |
| ...       | Graphical arguments passed to <a href="#">plot.spec</a> .                                         |

**Value**

An object of class "spec". The result is returned invisibly if plot is true.

**Warning**

Some authors, for example Thomson (1990), warn strongly that AR spectra can be misleading.

**Note**

The multivariate case is not yet implemented.

spec.ar(log(lynx), method = "burg", add = TRUE, col = "purple")
spec.ar(log(lynx), method = "mle", add = TRUE, col = "forest green")
spec.ar(log(lynx), method = "ols", add = TRUE, col = "blue")
```

---

spec.pgram

---

*Estimate Spectral Density of a Time Series by a Smoothed Periodogram*

---

**Description**

spec.pgram calculates the periodogram using a fast Fourier transform, and optionally smooths the result with a series of modified Daniell smoothers (moving averages giving half weight to the end values).

**Usage**

```
spec.pgram(x, spans = NULL, kernel, taper = 0.1,
           pad = 0, fast = TRUE, demean = FALSE, detrend = TRUE,
           plot = TRUE, na.action = na.fail, ...)
```

**Arguments**

|                        |                                                                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | univariate or multivariate time series.                                                                                                                |
| <code>spans</code>     | vector of odd integers giving the widths of modified Daniell smoothers to be used to smooth the periodogram.                                           |
| <code>kernel</code>    | alternatively, a kernel smoother of class "tskernel".                                                                                                  |
| <code>taper</code>     | specifies the proportion of data to taper. A split cosine bell taper is applied to this proportion of the data at the beginning and end of the series. |
| <code>pad</code>       | proportion of data to pad. Zeros are added to the end of the series to increase its length by the proportion <code>pad</code> .                        |
| <code>fast</code>      | logical; if TRUE, pad the series to a highly composite length.                                                                                         |
| <code>demean</code>    | logical. If TRUE, subtract the mean of the series.                                                                                                     |
| <code>detrend</code>   | logical. If TRUE, remove a linear trend from the series. This will also remove the mean.                                                               |
| <code>plot</code>      | plot the periodogram?                                                                                                                                  |
| <code>na.action</code> | NA action function.                                                                                                                                    |
| <code>...</code>       | graphical arguments passed to <code>plot.spec</code> .                                                                                                 |

**Details**

The raw periodogram is not a consistent estimator of the spectral density, but adjacent values are asymptotically independent. Hence a consistent estimator can be derived by smoothing the raw periodogram, assuming that the spectral density is smooth.

The series will be automatically padded with zeros until the series length is a highly composite number in order to help the Fast Fourier Transform. This is controlled by the `fast` and not the `pad` argument.

The periodogram at zero is in theory zero as the mean of the series is removed (but this may be affected by tapering): it is replaced by an interpolation of adjacent values during smoothing, and no value is returned for that frequency.

**Value**

A list object of class "spec" (see [spectrum](#)) with the following additional components:

|                        |                                                                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kernel</code>    | The kernel argument, or the kernel constructed from <code>spans</code> .                                                                             |
| <code>df</code>        | The distribution of the spectral density estimate can be approximated by a (scaled) chi square distribution with <code>df</code> degrees of freedom. |
| <code>bandwidth</code> | The equivalent bandwidth of the kernel smoother as defined by Bloomfield (1976, page 201).                                                           |

|         |                                    |
|---------|------------------------------------|
| taper   | The value of the taper argument.   |
| pad     | The value of the pad argument.     |
| detrend | The value of the detrend argument. |
| demean  | The value of the demean argument.  |

The result is returned invisibly if plot is true.

|------------|---------------------------------------------|
| spec.taper | <i>Taper a Time Series by a Cosine Bell</i> |
|------------|---------------------------------------------|

---

**Description**

Apply a cosine-bell taper to a time series.

**Usage**

```
spec.taper(x, p = 0.1)
```

**Arguments**

- x                    A univariate or multivariate time series
- p                    The proportion to be tapered at each end of the series, either a scalar (giving the proportion for all series) or a vector of the length of the number of series (giving the proportion for each series..

**Details**

The cosine-bell taper is applied to the first and last `p[i]` observations of time series `x[, i]`.

**Value**

A new time series object.

|----------|------------------------------------|
| spectrum | <i>Spectral Density Estimation</i> |
|----------|------------------------------------|

---

**Description**

The spectrum function estimates the spectral density of a time series.

**Usage**

```
spectrum(x, ..., method = c("pgram", "ar"))
```

**Arguments**

|        |                                                                                                                                             |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------|
| x      | A univariate or multivariate time series.                                                                                                   |
| method | String specifying the method used to estimate the spectral density. Allowed methods are "pgram" (the default) and "ar". Can be abbreviated. |
| ...    | Further arguments to specific spec methods or plot.spec.                                                                                    |

**Details**

spectrum is a wrapper function which calls the methods `spec.pgram` and `spec.ar`.

The spectrum here is defined with scaling  $1/\text{frequency}(x)$ , following S-PLUS. This makes the spectral density a density over the range  $(-\text{frequency}(x)/2, +\text{frequency}(x)/2]$ , whereas a more common scaling is  $2\pi$  and range  $(-0.5, 0.5]$  (e.g., Bloomfield) or 1 and range  $(-\pi, \pi]$ .

If available, a confidence interval will be plotted by `plot.spec`: this is asymmetric, and the width of the centre mark indicates the equivalent bandwidth.

**Value**

An object of class "spec", which is a list containing at least the following components:

|        |                                                                                                                                                                                                                                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| freq   | vector of frequencies at which the spectral density is estimated. (Possibly approximate Fourier frequencies.) The units are the reciprocal of cycles per unit time (and not per observation spacing): see 'Details' below.                                      |
| spec   | Vector (for univariate series) or matrix (for multivariate series) of estimates of the spectral density at frequencies corresponding to freq.                                                                                                                   |
| coh    | NULL for univariate series. For multivariate time series, a matrix containing the <i>squared</i> coherency between different series. Column $i + (j - 1) * (j - 2) / 2$ of coh contains the squared coherency between columns $i$ and $j$ of x, where $i < j$ . |
| phase  | NULL for univariate series. For multivariate time series a matrix containing the cross-spectrum phase between different series. The format is the same as coh.                                                                                                  |
| series | The name of the time series.                                                                                                                                                                                                                                    |
| snames | For multivariate input, the names of the component series.                                                                                                                                                                                                      |
| method | The method used to calculate the spectrum.                                                                                                                                                                                                                      |

The result is returned invisibly if plot is true.

**Note**

The default plot for objects of class "spec" is quite complex, including an error bar and default title, subtitle and axis labels. The defaults can all be overridden by supplying the appropriate graphical parameters.

## splinefun

## Interpolating Splines

**Description**

Perform cubic (or Hermite) spline interpolation of given data points, returning either a list of points obtained by the interpolation or a *function* performing the interpolation.

**Usage**

```
splinefun(x, y = NULL,
          method = c("fmm", "periodic", "natural", "monoH.FC", "hyman"),
          ties = mean)
```

```
spline(x, y = NULL, n = 3*length(x), method = "fmm",
       xmin = min(x), xmax = max(x), xout, ties = mean)
```

```
splinefunH(x, y, m)
```

**Arguments**

|                         |                                                                                                                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>       | vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see <a href="#">xy.coords</a> .<br>y must be increasing or decreasing for method = "hyman". |
| <code>m</code>          | (for splinefunH()): vector of <i>slopes</i> $m_i$ at the points $(x_i, y_i)$ ; these together determine the <b>H</b> ermite “spline” which is piecewise cubic, (only) <i>once</i> differentiable continuously.           |
| <code>method</code>     | specifies the type of spline to be used. Possible values are "fmm", "natural", "periodic", "monoH.FC" and "hyman". Can be abbreviated.                                                                                   |
| <code>n</code>          | if xout is left unspecified, interpolation takes place at n equally spaced points spanning the interval [xmin, xmax].                                                                                                    |
| <code>xmin, xmax</code> | left-hand and right-hand endpoint of the interpolation interval (when xout is unspecified).                                                                                                                              |
| <code>xout</code>       | an optional set of values specifying where interpolation is to take place.                                                                                                                                               |
| <code>ties</code>       | Handling of tied x values. Either a function with a single vector argument returning a single number result or the string "ordered".                                                                                     |

**Details**

The inputs can contain missing values which are deleted, so at least one complete (x, y) pair is required. If method = "fmm", the spline used is that of Forsythe, Malcolm and Moler (an exact cubic is fitted through the four points at each end of the data, and this is used to determine the end conditions). Natural splines are used when method = "natural", and periodic splines when method = "periodic".

The method "monoH.FC" computes a *monotone* Hermite spline according to the method of Fritsch and Carlson. It does so by determining slopes such that the Hermite spline, determined by  $(x_i, y_i, m_i)$ , is monotone (increasing or decreasing) **iff** the data are.

Method "hyman" computes a *monotone* cubic spline using Hyman filtering of an method = "fmm" fit for strictly monotonic inputs. (Added in R 2.15.2.)

These interpolation splines can also be used for extrapolation, that is prediction at points outside the range of  $x$ . Extrapolation makes little sense for method = "fmm"; for natural splines it is linear using the slope of the interpolating curve at the nearest data point.

### Value

spline returns a list containing components  $x$  and  $y$  which give the ordinates where interpolation took place and the interpolated values.

splinefun returns a function with formal arguments  $x$  and  $deriv$ , the latter defaulting to zero. This function can be used to evaluate the interpolating cubic spline ( $deriv = 0$ ), or its derivatives ( $deriv = 1, 2, 3$ ) at the points  $x$ , where the spline function interpolates the data points originally specified. It uses data stored in its environment when it was created, the details of which are subject to change.

### Warning

The value returned by splinefun contains references to the code in the current version of R: it is not intended to be saved and loaded into a different R session. This is safer in R  $\geq 3.0.0$ .

### Author(s)

R Core Team.

Simon Wood for the original code for Hyman filtering.

## here, and both are 'much worse' than the regular fmm spline.

```

---

SSasymp

*Self-Starting Nls Asymptotic Regression Model*

---

## Description

This selfStart model evaluates the asymptotic regression function and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym, R0, and lrc for a given set of data.

## Usage

```
SSasymp(input, Asym, R0, lrc)
```

Arguments

|       |                                                                                                           |
|-------|-----------------------------------------------------------------------------------------------------------|
| input | a numeric vector of values at which to evaluate the model.                                                |
| Asym  | a numeric parameter representing the horizontal asymptote on the right side (very large values of input). |
| R0    | a numeric parameter representing the response when input is zero.                                         |
| lrc   | a numeric parameter representing the natural logarithm of the rate constant.                              |

Value

a numeric vector of the same length as input. It is the value of the expression  $Asym + (R0 - Asym) * \exp(-\exp(lrc) * input)$ . If all of the arguments Asym, R0, and lrc are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

|-----------|---------------------------------------------------------------------|
| SSasypOff | <i>Self-Starting Nls Asymptotic Regression Model with an Offset</i> |
|-----------|---------------------------------------------------------------------|

---

Description

This selfStart model evaluates an alternative parametrization of the asymptotic regression function and the gradient with respect to those parameters. It has an initial attribute that creates initial estimates of the parameters Asym, lrc, and c0.

Usage

```
SSasypOff(input, Asym, lrc, c0)
```

**Arguments**

|                    |                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                                |
| <code>Asym</code>  | a numeric parameter representing the horizontal asymptote on the right side (very large values of input). |
| <code>lrc</code>   | a numeric parameter representing the natural logarithm of the rate constant.                              |
| <code>c0</code>    | a numeric parameter representing the input for which the response is zero.                                |

**Value**

a numeric vector of the same length as `input`. It is the value of the expression `Asym*(1 - exp(-exp(lrc)*(input - c0)))`. If all of the arguments `Asym`, `lrc`, and `c0` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSbiexp

*Self-Starting Nls Biexponential model*

---

**Description**

This `selfStart` model evaluates the biexponential model function and its gradient. It has an initial attribute that creates initial estimates of the parameters `A1`, `lrc1`, `A2`, and `lrc2`.

**Usage**

```
SSbiexp(input, A1, lrc1, A2, lrc2)
```

**Arguments**

|                    |                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                             |
| <code>A1</code>    | a numeric parameter representing the multiplier of the first exponential.                              |
| <code>lrc1</code>  | a numeric parameter representing the natural logarithm of the rate constant of the first exponential.  |
| <code>A2</code>    | a numeric parameter representing the multiplier of the second exponential.                             |
| <code>lrc2</code>  | a numeric parameter representing the natural logarithm of the rate constant of the second exponential. |

**Value**

a numeric vector of the same length as `input`. It is the value of the expression  $A1 \cdot \exp(-\exp(lrc1) \cdot \text{input}) + A2 \cdot \exp(-\exp(lrc2) \cdot \text{input})$ . If all of the arguments `A1`, `lrc1`, `A2`, and `lrc2` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

|-----|------------------------------------------------------------------------|
| SSD | <i>SSD Matrix and Estimated Variance Matrix in Multivariate Models</i> |
|-----|------------------------------------------------------------------------|

---

**Description**

Functions to compute matrix of residual sums of squares and products, or the estimated variance matrix for multivariate linear models.

**Usage**

```
# S3 method for class 'mlm'
SSD(object, ...)

# S3 methods for class 'SSD' and 'mlm'
estVar(object, ...)
```

**Arguments**

|        |                                                        |
|--------|--------------------------------------------------------|
| object | object of class "mlm", or "SSD" in the case of estVar. |
| ...    | Unused                                                 |

**Value**

SSD() returns a list of class "SSD" containing the following components

|      |                                                  |
|------|--------------------------------------------------|
| SSD  | The residual sums of squares and products matrix |
| df   | Degrees of freedom                               |
| call | Copied from object                               |

estVar returns a matrix with the estimated variances and covariances.

|-------|--------------------------------------------------------|
| SSfol | <i>Self-Starting Nls First-order Compartment Model</i> |
|-------|--------------------------------------------------------|

---

Description

This selfStart model evaluates the first-order compartment function and its gradient. It has an initial attribute that creates initial estimates of the parameters lKe, lKa, and lCl.

Usage

```
SSfol(Dose, input, lKe, lKa, lCl)
```

Arguments

|       |                                                                                          |
|-------|------------------------------------------------------------------------------------------|
| Dose  | a numeric value representing the initial dose.                                           |
| input | a numeric vector at which to evaluate the model.                                         |
| lKe   | a numeric parameter representing the natural logarithm of the elimination rate constant. |
| lKa   | a numeric parameter representing the natural logarithm of the absorption rate constant.  |
| lCl   | a numeric parameter representing the natural logarithm of the clearance.                 |

**Value**

a numeric vector of the same length as input, which is the value of the expression

$$\frac{\text{Dose} * \exp(\text{lKe} + \text{lKa} - \text{lCl}) * (\exp(-\exp(\text{lKe}) * \text{input}) - \exp(-\exp(\text{lKa}) * \text{input}))}{(\exp(\text{lKa}) - \exp(\text{lKe}))}$$

If all of the arguments lKe, lKa, and lCl are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

| Asym  | a numeric parameter representing the asymptote.                                                                                    |
| xmid  | a numeric parameter representing the x value at the inflection point of the curve.<br>The value of SSlogis will be Asym/2 at xmid. |
| scal  | a numeric scale parameter on the input axis.                                                                                       |

**Value**

a numeric vector of the same length as input. It is the value of the expression  $\text{Asym}/(1+\exp((\text{xmid}-\text{input})/\text{scal}))$ . If all of the arguments Asym, xmid, and scal are names of objects the gradient matrix with respect to these names is attached as an attribute named gradient.

SSmicmen

*Self-Starting Nls Michaelis-Menten Model*

---

**Description**

This selfStart model evaluates the Michaelis-Menten model and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Vm and K

**Usage**

```
SSmicmen(input, Vm, K)
```

**Arguments**

|       |                                                                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| input | a numeric vector of values at which to evaluate the model.                                                                                                               |
| Vm    | a numeric parameter representing the maximum value of the response.                                                                                                      |
| K     | a numeric parameter representing the input value at which half the maximum response is attained. In the field of enzyme kinetics this is called the Michaelis parameter. |

Value

a numeric vector of the same length as input. It is the value of the expression  $Vm * input / (K + input)$ . If both the arguments Vm and K are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

|           |                                                     |
|-----------|-----------------------------------------------------|
| SSweibull | <i>Self-Starting Nls Weibull Growth Curve Model</i> |
|-----------|-----------------------------------------------------|

---

Description

This selfStart model evaluates the Weibull model for growth curve data and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym, Drop, lrc, and pwr for a given set of data.

Usage

```
SSweibull(x, Asym, Drop, lrc, pwr)
```

Arguments

- |      |                                                                                                       |
|------|-------------------------------------------------------------------------------------------------------|
| x    | a numeric vector of values at which to evaluate the model.                                            |
| Asym | a numeric parameter representing the horizontal asymptote on the right side (very small values of x). |
| Drop | a numeric parameter representing the change from Asym to the y intercept.                             |

lrc                    a numeric parameter representing the natural logarithm of the rate constant.  
 pwr                   a numeric parameter representing the power to which x is raised.

### Details

This model is a generalization of the [SSasympt](#) model in that it reduces to SSasympt when pwr is unity.

### Value

a numeric vector of the same length as x. It is the value of the expression  $\text{Asym} - \text{Drop} * \exp(-\exp(\text{lrc}) * x^{\text{pwr}})$ . If all of the arguments Asym, Drop, lrc, and pwr are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

### Examples

```
Chick.6 <- subset(ChickWeight, (Chick == 6) & (Time > 0))
SSweibull(Chick.6$Time, 160, 115, -5.5, 2.5) # response only
Asym <- 160; Drop <- 115; lrc <- -5.5; pwr <- 2.5
SSweibull(Chick.6$Time, Asym, Drop, lrc, pwr) # response and gradient
getInitial(weight ~ SSweibull(Time, Asym, Drop, lrc, pwr), data = Chick.6)
## Initial values are in fact the converged values
fm1 <- nls(weight ~ SSweibull(Time, Asym, Drop, lrc, pwr), data = Chick.6)
summary(fm1)
```

---

start

*Encode the Terminal Times of Time Series*

---

### Description

Extract and encode the times the first and last observations were taken. Provided only for compatibility with S version 2.

**Usage**

```
start(x, ...)
end(x, ...)
```

**Arguments**

x                    a univariate or multivariate time-series, or a vector or matrix.  
...                   extra arguments for future methods.

**Details**

These are generic functions, which will use the [tsp](#) attribute of x if it exists. Their default methods decode the start time from the original time units, so that for a monthly series 1995.5 is represented as c(1995, 7). For a series of frequency f, time n+i/f is presented as c(n, i+1) (even for i = 0 and f = 1).

**Warning**

The representation used by start and end has no meaning unless the frequency is supplied.

|------------|-----------------------------|
| stat.anova | <i>GLM Anova Statistics</i> |
|------------|-----------------------------|

---

**Description**

This is a utility function, used in lm and glm methods for [anova\(..., test != NULL\)](#) and should not be used by the average user.

**Usage**

```
stat.anova(table, test = c("Rao","LRT", "Chisq", "F", "Cp"),
            scale, df.scale, n)
```

**Arguments**

table                numeric matrix as results from [anova.glm\(..., test = NULL\)](#).  
test                  a character string, partially matching one of "Rao", "LRT", "Chisq", "F" or "Cp".  
scale                a residual mean square or other scale estimate to be used as the denominator in an F test.  
df.scale             degrees of freedom corresponding to scale.  
n                    number of observations.

**Value**

A matrix which is the original table, augmented by a column of test statistics, depending on the test argument.

**Examples**

```
##-- Continued from '?glm':

print(ag <- anova(glm.D93))
stat.anova(ag$table, test = "Cp",
           scale = sum(resid(glm.D93, "pearson")^2)/4,
           df.scale = 4, n = 9)
```

---

stats-deprecated

*Deprecated Functions in Package stats*

---

**Description**

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as the next release.

**Usage**

```
plclust(tree, hang = 0.1, unit = FALSE, level = FALSE, hmin = 0,
        square = TRUE, labels = NULL, plot. = TRUE,
        axes = TRUE, frame.plot = FALSE, ann = TRUE,
        main = "", sub = NULL, xlab = NULL, ylab = "Height")
```

**Arguments**

|        |                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tree   | an object of the type produced by <a href="#">hclust</a> .                                                                                                                                   |
| hang   | The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.                                          |
| unit   | logical. If true, the splits are plotted at equally-spaced heights rather than at the height in the object.                                                                                  |
| labels | A character vector of labels for the leaves of the tree. By default the row names or row numbers of the original data are used. If <code>labels = FALSE</code> no labels at all are plotted. |

axes, frame.plot, ann  
logical flags as in [plot.default](#).  
main, sub, xlab, ylab  
character strings for [title](#). sub and xlab have a non-NULL default when there's a tree\$call.  
...  
Further graphical arguments. E.g., cex controls the size of the labels (if plotted) in the same way as [text](#).  
hmin  
numeric. All heights less than hmin are regarded as being hmin: this can be used to suppress detail at the bottom of the tree.  
level, square, plot.  
unimplemented arguments for S-PLUS compatibility.

Details

plcust is a deprecated wrapper for the plot method for [hclust](#), provided long ago for S-PLUS compatibility.

|      |                                                      |
|------|------------------------------------------------------|
| step | <i>Choose a model by AIC in a Stepwise Algorithm</i> |
|------|------------------------------------------------------|

---

Description

Select a formula-based model by AIC.

Usage

```
step(object, scope, scale = 0,  
      direction = c("both", "backward", "forward"),  
      trace = 1, keep = NULL, steps = 1000, k = 2, ...)
```

Arguments

|        |                                                                                                                                                                                                                                                                   |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object representing a model of an appropriate class (mainly "lm" and "glm"). This is used as the initial model in the stepwise search.                                                                                                                         |
| scope  | defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components upper and lower, both formulae. See the details for how to specify the formulae and how they are used.                       |
| scale  | used in the definition of the AIC statistic for selecting the models, currently only for <a href="#">lm</a> , <a href="#">aov</a> and <a href="#">glm</a> models. The default value, 0, indicates the scale should be estimated: see <a href="#">extractAIC</a> . |

|           |                                                                                                                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| direction | the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the scope argument is missing the default for direction is "backward". Values can be abbreviated.                                       |
| trace     | if positive, information is printed during the running of step. Larger values may give more detailed information.                                                                                                                                 |
| keep      | a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically keep will select a subset of the components of the object and return them. The default is not to keep anything. |
| steps     | the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.                                                                                              |
| k         | the multiple of the number of degrees of freedom used for the penalty. Only $k = 2$ gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.                                                                                  |
| ...       | any additional arguments to <code>extractAIC</code> .                                                                                                                                                                                             |

### Details

step uses `add1` and `drop1` repeatedly; it will work for any method for which they work, and that is determined by having a valid method for `extractAIC`. When the additive constant can be chosen so that AIC is equal to Mallows'  $C_p$ , this is done and the tables are labelled appropriately.

The set of models searched is determined by the scope argument. The right-hand-side of its lower component is always included in the model, and right-hand-side of the model is included in the upper component. If scope is a single formula, it specifies the upper component, and the lower model is empty. If scope is missing, the initial model is used as the upper model.

Models specified by scope can be templates to update object as used by `update.formula`. So using `.` in a scope formula means 'what is already there', with `.^2` indicating all interactions of existing terms.

There is a potential problem in using `glm` fits with a variable scale, as in that case the deviance is not simply related to the maximized log-likelihood. The "glm" method for function `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The binomial and poisson families have fixed scale by default and do not correspond to a particular maximum-likelihood problem for variable scale.)

### Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep=` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

### Warning

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and R's default of `na.action = na.omit` is used. We suggest you remove the missing values first.

Calls to the function `nobs` are used to check that the number of observations involved in the fitting process remains unchanged.

### Note

This function differs considerably from the function in S, which uses a number of approximations and does not in general compute the correct AIC.

This is a minimal implementation. Use `stepAIC` in package **MASS** for a wider range of object classes.

### Author(s)

B. D. Ripley: `step` is a slightly simplified version of `stepAIC` in package **MASS** (Venables & Ripley, 2002 and earlier editions).

The idea of a step function follows that described in Hastie & Pregibon (1992); but the implementation in R is more general.

### Examples

```
## following on from example(lm)

step(lm.D9)

summary(lm1 <- lm(Fertility ~ ., data = swiss))
slm1 <- step(lm1)
summary(slm1)
slm1$anova
```

## Description

Given the vectors  $(x_1, \dots, x_n)$  and  $(y_0, y_1, \dots, y_n)$  (one value more!), `stepfun(x, y, ...)` returns an interpolating ‘step’ function, say `fn`. I.e.,  $fn(t) = c_i$  (constant) for  $t \in (x_i, x_{i+1})$  and at the abscissa values, if (by default) `right = FALSE`,  $fn(x_i) = y_i$  and for `right = TRUE`,  $fn(x_i) = y_{i-1}$ , for  $i = 1, \dots, n$ .

The value of the constant  $c_i$  above depends on the ‘continuity’ parameter `f`. For the default, `right = FALSE`, `f = 0`, `fn` is a *cadlag* function, i.e., continuous from the right, limits from the left, so that the function is piecewise constant on intervals that include their *left* endpoint. In general,  $c_i$  is interpolated in between the neighbouring  $y$  values,  $c_i = (1-f)y_i + f \cdot y_{i+1}$ . Therefore, for non-0 values of `f`, `fn` may no longer be a proper step function, since it can be discontinuous from both sides, unless `right = TRUE`, `f = 1` which is left-continuous (i.e., constant pieces contain their right endpoint).

## Usage

```
stepfun(x, y, f = as.numeric(right), ties = "ordered",
        right = FALSE)
```

```
is.stepfun(x)
knots(Fn, ...)
as.stepfun(x, ...)
```

```
## S3 method for class 'stepfun'
print(x, digits = getOption("digits") - 2, ...)
```

```
## S3 method for class 'stepfun'
summary(object, ...)
```

## Arguments

|                         |                                                                                                                                                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | numeric vector giving the knots or jump locations of the step function for <code>stepfun()</code> . For the other functions, <code>x</code> is as object below. |
| <code>y</code>          | numeric vector one longer than <code>x</code> , giving the heights of the function values <i>between</i> the <code>x</code> values.                             |
| <code>f</code>          | a number between 0 and 1, indicating how interpolation outside the given <code>x</code> values should happen. See <a href="#">approxfun</a> .                   |
| <code>ties</code>       | Handling of tied <code>x</code> values. Either a function or the string "ordered". See <a href="#">approxfun</a> .                                              |
| <code>right</code>      | logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.                                                        |
| <code>Fn, object</code> | an R object inheriting from "stepfun".                                                                                                                          |
| <code>digits</code>     | number of significant digits to use, see <a href="#">print</a> .                                                                                                |
| <code>...</code>        | potentially further arguments (required by the generic).                                                                                                        |

**Value**

A function of class "stepfun", say `fn`.

There are methods available for summarizing ("`summary(.)`"), representing ("`print(.)`") and plotting ("`plot(.)`", see [plot.stepfun](#)) "stepfun" objects.

The [environment](#) of `fn` contains all the information needed;

|                   |                                                             |
|-------------------|-------------------------------------------------------------|
| "x", "y"          | the original arguments                                      |
| "n"               | number of knots (x values)                                  |
| "f"               | continuity parameter                                        |
| "yleft", "yright" | the function values <i>outside</i> the knots                |
| "method"          | (always == "constant", from <a href="#">approxfun(.)</a> ). |

The knots are also available via [knots](#)(`fn`).

**Note**

The objects of class "stepfun" are not intended to be used for permanent storage and may change structure between versions of R (and did at R 3.0.0). They can usually be re-created by

```
eval(attr(old_obj, "call"), environment(old_obj))
```

since the data used is stored as part of the object's environment.

---

stl

---

*Seasonal Decomposition of Time Series by Loess*

---

## Description

Decompose a time series into seasonal, trend and irregular components using loess, acronym STL.

## Usage

```

stl(x, s.window, s.degree = 0,
    t.window = NULL, t.degree = 1,
    l.window = nextodd(period), l.degree = t.degree,
    s.jump = ceiling(s.window/10),
    t.jump = ceiling(t.window/10),
    l.jump = ceiling(l.window/10),
    robust = FALSE,
    inner = if(robust) 1 else 2,
    outer = if(robust) 15 else 0,
    na.action = na.fail)

```

## Arguments

|          |                                                                                                                                                                                                                                                                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x        | univariate time series to be decomposed. This should be an object of class "ts" with a frequency greater than one.                                                                                                                                                                                                                                   |
| s.window | either the character string "periodic" or the span (in lags) of the loess window for seasonal extraction, which should be odd and at least 7, according to Cleveland et al. This has no default.                                                                                                                                                     |
| s.degree | degree of locally-fitted polynomial in seasonal extraction. Should be zero or one.                                                                                                                                                                                                                                                                   |
| t.window | the span (in lags) of the loess window for trend extraction, which should be odd. If NULL, the default, <code>nextodd(ceiling((1.5*period) / (1-(1.5/s.window))))</code> , is taken.                                                                                                                                                                 |
| t.degree | degree of locally-fitted polynomial in trend extraction. Should be zero or one.                                                                                                                                                                                                                                                                      |
| l.window | the span (in lags) of the loess window of the low-pass filter used for each subseries. Defaults to the smallest odd integer greater than or equal to <code>frequency(x)</code> which is recommended since it prevents competition between the trend and seasonal components. If not an odd integer its given value is increased to the next odd one. |

|                        |                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| l.degree               | degree of locally-fitted polynomial for the subseries low-pass filter. Must be 0 or 1.                                         |
| s.jump, t.jump, l.jump | integers at least one to increase speed of the respective smoother. Linear interpolation happens between every *.jumpth value. |
| robust                 | logical indicating if robust fitting be used in the loess procedure.                                                           |
| inner                  | integer; the number of 'inner' (backfitting) iterations; usually very few (2) iterations suffice.                              |
| outer                  | integer; the number of 'outer' robustness iterations.                                                                          |
| na.action              | action on missing values.                                                                                                      |

### Details

The seasonal component is found by *loess* smoothing the seasonal sub-series (the series of all January values, ...); if `s.window = "periodic"` smoothing is effectively replaced by taking the mean. The seasonal values are removed, and the remainder smoothed to find the trend. The overall level is removed from the seasonal component and added to the trend component. This process is iterated a few times. The remainder component is the residuals from the seasonal plus trend fit.

Several methods for the resulting class "stl" objects, see, [plot.stl](#).

### Value

stl returns an object of class "stl" with components

|             |                                                                                    |
|-------------|------------------------------------------------------------------------------------|
| time.series | a multiple time series with columns seasonal, trend and remainder.                 |
| weights     | the final robust weights (all one if fitting is not done robustly).                |
| call        | the matched call.                                                                  |
| win         | integer (length 3 vector) with the spans used for the "s", "t", and "l" smoothers. |
| deg         | integer (length 3) vector with the polynomial degrees for these smoothers.         |
| jump        | integer (length 3) vector with the 'jumps' (skips) used for these smoothers.       |
| ni          | number of inner iterations                                                         |
| no          | number of outer robustness iterations                                              |

### Note

This is similar to but not identical to the `stl` function in S-PLUS. The remainder component given by S-PLUS is the sum of the trend and remainder series from this function.

**Examples**

```
require(graphics)

plot(stl(nottem, "per"))
plot(stl(nottem, s.window = 7, t.window = 50, t.jump = 1))

plot(stllc <- stl(log(co2), s.window = 21))
summary(stllc)
## linear trend, strict period.
plot(stl(log(co2), s.window = "per", t.window = 1000))

## Two STL plotted side by side :
  stmd <- stl(mdeaths, s.window = "per") # non-robust
summary(stmR <- stl(mdeaths, s.window = "per", robust = TRUE))
op <- par(mar = c(0, 4, 0, 3), oma = c(5, 0, 4, 0), mfcol = c(4, 2))
plot(stmd, set.pars = NULL, labels = NULL,
     main = "stl(mdeaths, s.w = \"per\", robust = FALSE / TRUE )")
plot(stmR, set.pars = NULL)
# mark the 'outliers' :
(i0 <- which(stmR $ weights < 1e-8)) # 10 were considered outliers
sts <- stmR$time.series
points(time(sts)[i0], 0.8* sts[,"remainder"][i0], pch = 4, col = "red")
par(op) # reset
```

stlmethods

*Methods for STL Objects***Description**

Methods for objects of class `stl`, typically the result of [stl](#). The plot method does a multiple figure plot with some flexibility.

There are also (non-visible) print and summary methods.

**Usage**

```
## S3 method for class 'stl'
plot(x, labels = colnames(X),
     set.pars = list(mar = c(0, 6, 0, 6), oma = c(6, 0, 4, 0),
                    tck = -0.01, mfrow = c(nplot, 1)),
     main = NULL, range.bars = TRUE, ...,
     col.range = "light gray")
```

**Arguments**

|                         |                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | <code>stl</code> object.                                                                                                 |
| <code>labels</code>     | character of length 4 giving the names of the component time-series.                                                     |
| <code>set.pars</code>   | settings for <code>par(.)</code> when setting up the plot.                                                               |
| <code>main</code>       | plot main title.                                                                                                         |
| <code>range.bars</code> | logical indicating if each plot should have a bar at its right side which are of equal heights in user coordinates.      |
| <code>...</code>        | further arguments passed to or from other methods.                                                                       |
| <code>col.range</code>  | colour to be used for the range bars, if plotted. Note this appears after <code>...</code> and so cannot be abbreviated. |

**See Also**

`plot.ts` and `stl`, particularly for examples.

---

StructTS

*Fit Structural Time Series*

---

**Description**

Fit a structural model for a time series by maximum likelihood.

**Usage**

```
StructTS(x, type = c("level", "trend", "BSM"), init = NULL,
         fixed = NULL, optim.control = NULL)
```

**Arguments**

|                            |                                                                                                                                                                                                      |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>             | a univariate numeric time series. Missing values are allowed.                                                                                                                                        |
| <code>type</code>          | the class of structural model. If omitted, a BSM is used for a time series with $\text{frequency}(x) > 1$ , and a local trend model otherwise. Can be abbreviated.                                   |
| <code>init</code>          | initial values of the variance parameters.                                                                                                                                                           |
| <code>fixed</code>         | optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in <code>fixed</code> will be varied. Probably most useful for setting variances to zero. |
| <code>optim.control</code> | List of control parameters for <code>optim</code> . Method "L-BFGS-B" is used.                                                                                                                       |

## Details

*Structural time series* models are (linear Gaussian) state-space models for (univariate) time series based on a decomposition of the series into a number of components. They are specified by a set of error variances, some of which may be zero.

The simplest model is the *local level* model specified by `type = "level"`. This has an underlying level  $\mu_t$  which evolves by

$$\mu_{t+1} = \mu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)$$

The observations are

$$x_t = \mu_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)$$

There are two parameters,  $\sigma_\xi^2$  and  $\sigma_\epsilon^2$ . It is an ARIMA(0,1,1) model, but with restrictions on the parameter set.

The *local linear trend model*, `type = "trend"`, has the same measurement equation, but with a time-varying slope in the dynamics for  $\mu_t$ , given by

$$\mu_{t+1} = \mu_t + \nu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)$$

$$\nu_{t+1} = \nu_t + \zeta_t, \quad \zeta_t \sim N(0, \sigma_\zeta^2)$$

with three variance parameters. It is not uncommon to find  $\sigma_\zeta^2 = 0$  (which reduces to the local level model) or  $\sigma_\xi^2 = 0$ , which ensures a smooth trend. This is a restricted ARIMA(0,2,2) model.

The *basic structural model*, `type = "BSM"`, is a local trend model with an additional seasonal component. Thus the measurement equation is

$$x_t = \mu_t + \gamma_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)$$

where  $\gamma_t$  is a seasonal component with dynamics

$$\gamma_{t+1} = -\gamma_t + \dots + \gamma_{t-s+2} + \omega_t, \quad \omega_t \sim N(0, \sigma_\omega^2)$$

The boundary case  $\sigma_\omega^2 = 0$  corresponds to a deterministic (but arbitrary) seasonal pattern. (This is sometimes known as the ‘dummy variable’ version of the BSM.)

## Value

A list of class "StructTS" with components:

|                        |                                                                                                                                                                                                                                   |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>coef</code>      | the estimated variances of the components.                                                                                                                                                                                        |
| <code>loglik</code>    | the maximized log-likelihood. Note that as all these models are non-stationary this includes a diffuse prior for some observations and hence is not comparable to <a href="#">arima</a> nor different types of structural models. |
| <code>loglik0</code>   | the maximized log-likelihood with the constant used prior to R 3.0.0, for backwards compatibility.                                                                                                                                |
| <code>data</code>      | the time series <code>x</code> .                                                                                                                                                                                                  |
| <code>residuals</code> | the standardized residuals.                                                                                                                                                                                                       |
| <code>fitted</code>    | a multiple time series with one component for the level, slope and seasonal components, estimated contemporaneously (that is at time $t$ and not at the end of the series).                                                       |

|               |                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| call          | the matched call.                                                                                                                                            |
| series        | the name of the series x.                                                                                                                                    |
| code          | the convergence code returned by <a href="#">optim</a> .                                                                                                     |
| model, model0 | Lists representing the Kalman Filter used in the fitting. See <a href="#">KalmanLike</a> . model0 is the initial state of the filter, model its final state. |
| xtsp          | the tsp attributes of x.                                                                                                                                     |

### Note

Optimization of structural models is a lot harder than many of the references admit. For example, the [AirPassengers](#) data are considered in Brockwell & Davis (1996): their solution appears to be a local maximum, but nowhere near as good a fit as that produced by StructTS. It is quite common to find fits with one or more variances zero, and this can include  $\sigma_\epsilon^2$ .

|-------------|------------------------------------------------|
| summary.aov | <i>Summarize an Analysis of Variance Model</i> |
|-------------|------------------------------------------------|

---

**Description**

Summarize an analysis of variance model.

**Usage**

```
## S3 method for class 'aov'
summary(object, intercept = FALSE, split,
        expand.split = TRUE, keep.zero.df = TRUE, ...)

## S3 method for class 'aovlist'
summary(object, ...)
```

**Arguments**

|              |                                                                                                                                                                                        |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object       | An object of class "aov" or "aovlist".                                                                                                                                                 |
| intercept    | logical: should intercept terms be included?                                                                                                                                           |
| split        | an optional named list, with names corresponding to terms in the model. Each component is itself a list with integer components giving contrasts whose contributions are to be summed. |
| expand.split | logical: should the split apply also to interactions involving the factor?                                                                                                             |
| keep.zero.df | logical: should terms with no degrees of freedom be included?                                                                                                                          |
| ...          | Arguments to be passed to or from other methods, for summary.aovlist including those for summary.aov.                                                                                  |

**Value**

An object of class c("summary.aov", "listof") or "summary.aovlist" respectively.

For fits with a single stratum the result will be a list of ANOVA tables, one for each response (even if there is only one response): the tables are of class "anova" inheriting from class "data.frame". They have columns "Df", "Sum Sq", "Mean Sq", as well as "F value" and "Pr(>F)" if there are non-zero residual degrees of freedom. There is a row for each term in the model, plus one for "Residuals" if there are any.

For multistratum fits the return value is a list of such summaries, one for each stratum.

**Note**

The use of expand.split = TRUE is little tested: it is always possible to set it to FALSE and specify exactly all the splits required.

**See Also**

## Examples

```
## For a simple example see example(aov)

# Cochran and Cox (1957, p.164)
# 3x3 factorial with ordered factors, each is average of 12.
CC <- data.frame(
  y = c(449, 413, 326, 409, 358, 291, 341, 278, 312)/12,
  P = ordered(gl(3, 3)), N = ordered(gl(3, 1, 9))
)
CC.aov <- aov(y ~ N * P, data = CC, weights = rep(12, 9))
summary(CC.aov)

# Split both main effects into linear and quadratic parts.
summary(CC.aov, split = list(N = list(L = 1, Q = 2),
                              P = list(L = 1, Q = 2)))

# Split only the interaction
summary(CC.aov, split = list("N:P" = list(L.L = 1, Q = 2:4)))

# split on just one var
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)))
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)),
        expand.split = FALSE)
```

---

summary.glm

*Summarizing Generalized Linear Model Fits*

---

## Description

These functions are all [methods](#) for class `glm` or `summary.glm` objects.

## Usage

```
## S3 method for class 'glm'
summary(object, dispersion = NULL, correlation = FALSE,
        symbolic.cor = FALSE, ...)

## S3 method for class 'summary.glm'
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
```

## Arguments

|                         |                                                                                                                                                                                 |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>     | an object of class <code>"glm"</code> , usually, a result of a call to <a href="#">glm</a> .                                                                                    |
| <code>x</code>          | an object of class <code>"summary.glm"</code> , usually, a result of a call to <code>summary.glm</code> .                                                                       |
| <code>dispersion</code> | the dispersion parameter for the family used. Either a single numerical value or <code>NULL</code> (the default), when it is inferred from <code>object</code> (see ‘Details’). |

|              |                                                                                                                   |
|--------------|-------------------------------------------------------------------------------------------------------------------|
| correlation  | logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.                     |
| digits       | the number of significant digits to use when printing.                                                            |
| symbolic.cor | logical. If TRUE, print the correlations in a symbolic form (see <a href="#">symnum</a> ) rather than as numbers. |
| signif.stars | logical. If TRUE, 'significance stars' are printed for each coefficient.                                          |
| ...          | further arguments passed to or from other methods.                                                                |

## Details

`print.summary.glm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is TRUE. The coefficients component of the result gives the estimated coefficients and their estimated standard errors, together with their ratio. This third column is labelled `t ratio` if the dispersion is estimated, and `z ratio` if the dispersion is known (or fixed by the family). A fourth column gives the two-tailed p-value corresponding to the `t` or `z` ratio based on a Student `t` or Normal reference distribution. (It is possible that the dispersion is not known and there are no residual degrees of freedom from which to estimate it. In that case the estimate is NaN.)

Aliased coefficients are omitted in the returned object but restored by the `print` method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations `print(summary(object)$correlation)` directly.

The dispersion of a GLM is not used in the fitting process, but it is needed to find standard errors. If dispersion is not supplied or NULL, the dispersion is taken as 1 for the binomial and Poisson families, and otherwise estimated by the residual Chisquared statistic (calculated from cases with non-zero weights) divided by the residual degrees of freedom.

`summary` can be used with Gaussian `glm` fits to handle the case of a linear regression with known error variance, something not handled by [summary.lm](#).

## Value

`summary.glm` returns an object of class `"summary.glm"`, a list with components

|                             |                                                                                                       |
|-----------------------------|-------------------------------------------------------------------------------------------------------|
| <code>call</code>           | the component from <code>object</code> .                                                              |
| <code>family</code>         | the component from <code>object</code> .                                                              |
| <code>deviance</code>       | the component from <code>object</code> .                                                              |
| <code>contrasts</code>      | the component from <code>object</code> .                                                              |
| <code>df.residual</code>    | the component from <code>object</code> .                                                              |
| <code>null.deviance</code>  | the component from <code>object</code> .                                                              |
| <code>df.null</code>        | the component from <code>object</code> .                                                              |
| <code>deviance.resid</code> | the deviance residuals: see <a href="#">residuals.glm</a> .                                           |
| <code>coefficients</code>   | the matrix of coefficients, standard errors, z-values and p-values. Aliased coefficients are omitted. |
| <code>aliased</code>        | named logical vector showing if the original coefficients are aliased.                                |

|              |                                                                                                                                          |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------|
| dispersion   | either the supplied argument or the inferred/estimated dispersion if the latter is NULL.                                                 |
| df           | a 3-vector of the rank of the model and the number of residual degrees of freedom, plus number of coefficients (including aliased ones). |
| cov.unscaled | the unscaled (dispersion = 1) estimated covariance matrix of the estimated coefficients.                                                 |
| cov.scaled   | ditto, scaled by dispersion.                                                                                                             |
| correlation  | (only if correlation is true.) The estimated correlations of the estimated coefficients.                                                 |
| symbolic.cor | (only if correlation is true.) The value of the argument symbolic.cor.                                                                   |

---

*Summarizing Linear Model Fits*

---

**Description**

summary method for class "lm".

**Usage**

```
## S3 method for class 'lm'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

## S3 method for class 'summary.lm'
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
```

**Arguments**

|              |                                                                                                                   |
|--------------|-------------------------------------------------------------------------------------------------------------------|
| object       | an object of class "lm", usually, a result of a call to <a href="#">lm</a> .                                      |
| x            | an object of class "summary.lm", usually, a result of a call to summary.lm.                                       |
| correlation  | logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.                     |
| digits       | the number of significant digits to use when printing.                                                            |
| symbolic.cor | logical. If TRUE, print the correlations in a symbolic form (see <a href="#">symnum</a> ) rather than as numbers. |
| signif.stars | logical. If TRUE, 'significance stars' are printed for each coefficient.                                          |
| ...          | further arguments passed to or from other methods.                                                                |

## Details

`print.summary.lm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives ‘significance stars’ if `signif.stars` is `TRUE`.

Aliased coefficients are omitted in the returned object but restored by the `print` method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

## Value

The function `summary.lm` computes and returns a list of summary statistics of the fitted linear model given in `object`, using the components (list elements) `"call"` and `"terms"` from its argument, plus

|                           |                                                                                                                                                                            |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>residuals</code>    | the <i>weighted</i> residuals, the usual residuals rescaled by the square root of the weights specified in the call to <code>lm</code> .                                   |
| <code>coefficients</code> | a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value. Aliased coefficients are omitted. |
| <code>aliased</code>      | named logical vector showing if the original coefficients are aliased.                                                                                                     |
| <code>sigma</code>        | the square root of the estimated variance of the random error                                                                                                              |

$$\hat{\sigma}^2 = \frac{1}{n-p} \sum_i w_i R_i^2,$$

where  $R_i$  is the  $i$ -th residual, `residuals[i]`.

|                         |                                                                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>df</code>         | degrees of freedom, a 3-vector $(p, n-p, p^*)$ , the first being the number of non-aliased coefficients, the last being the total number of coefficients. |
| <code>fstatistic</code> | (for models including non-intercept terms) a 3-vector with the value of the F-statistic with its numerator and denominator degrees of freedom.            |
| <code>r.squared</code>  | $R^2$ , the ‘fraction of variance explained by the model’,                                                                                                |

$$R^2 = 1 - \frac{\sum_i R_i^2}{\sum_i (y_i - y^*)^2},$$

where  $y^*$  is the mean of  $y_i$  if there is an intercept and zero otherwise.

|                            |                                                                                                                                |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>adj.r.squared</code> | the above $R^2$ statistic ‘ <i>adjusted</i> ’, penalizing for higher $p$ .                                                     |
| <code>cov.unscaled</code>  | a $p \times p$ matrix of (unscaled) covariances of the $\hat{\beta}_j$ , $j = 1, \dots, p$ .                                   |
| <code>correlation</code>   | the correlation matrix corresponding to the above <code>cov.unscaled</code> , if <code>correlation = TRUE</code> is specified. |
| <code>symbolic.cor</code>  | (only if <code>correlation</code> is true.) The value of the argument <code>symbolic.cor</code> .                              |
| <code>na.action</code>     | from <code>object</code> , if present there.                                                                                   |

|                |                                                             |
|----------------|-------------------------------------------------------------|
| summary.manova | <i>Summary Method for Multivariate Analysis of Variance</i> |
|----------------|-------------------------------------------------------------|

---

Description

A summary method for class "manova".

Usage

```
## S3 method for class 'manova'
summary(object,
        test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy"),
        intercept = FALSE, tol = 1e-7, ...)
```

Arguments

- object           An object of class "manova" or an aov object with multiple responses.
- test            The name of the test statistic to be used. Partial matching is used so the name can be abbreviated.
- intercept       logical. If TRUE, the intercept term is included in the table.
- tol             tolerance to be used in deciding if the residuals are rank-deficient: see [qr](#).
- ...             further arguments passed to or from other methods.

Details

The summary.manova method uses a multivariate test statistic for the summary table. Wilks' statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987).

The table gives a transformation of the test statistic which has approximately an F distribution. The approximations used follow S-PLUS and SAS (the latter apart from some cases of the Hotelling–Lawley statistic), but many other distributional approximations exist: see Anderson (1984) and

Krzanowski and Marriott (1994) for further references. All four approximate F statistics are the same when the term being tested has one degree of freedom, but in other cases that for the Roy statistic is an upper bound.

The tolerance tol is applied to the QR decomposition of the residual correlation matrix (unless some response has essentially zero residuals, when it is unscaled). Thus the default value guards against very highly correlated responses: it can be reduced but doing so will allow rather inaccurate results and it will normally be better to transform the responses to remove the high correlation.

## Value

An object of class "summary.manova". If there is a positive residual degrees of freedom, this is a list with components

|             |                                                                                  |
|-------------|----------------------------------------------------------------------------------|
| row.names   | The names of the terms, the row names of the stats table if present.             |
| SS          | A named list of sums of squares and product matrices.                            |
| Eigenvalues | A matrix of eigenvalues.                                                         |
| stats       | A matrix of the statistics, approximate F value, degrees of freedom and P value. |

otherwise components row.names, SS and Df (degrees of freedom) for the terms (and not the residuals).

| x            | an object of class "summary.nls", usually the result of a call to summary.nls.                                    |
| correlation  | logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.                     |
| digits       | the number of significant digits to use when printing.                                                            |
| symbolic.cor | logical. If TRUE, print the correlations in a symbolic form (see <a href="#">symnum</a> ) rather than as numbers. |
| signif.stars | logical. If TRUE, 'significance stars' are printed for each coefficient.                                          |
| ...          | further arguments passed to or from other methods.                                                                |

## Details

The distribution theory used to find the distribution of the standard errors and of the residual standard error (for t ratios) is based on linearization and is approximate, maybe very approximate.

print.summary.nls tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if signif.stars is TRUE.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print summary(object)\$correlation directly.

Value

The function `summary.nls` computes and returns a list of summary statistics of the fitted model given in `object`, using the component "formula" from its argument, plus

- `residuals` the *weighted* residuals, the usual residuals rescaled by the square root of the weights specified in the call to `nls`.
- `coefficients` a  $p \times 4$  matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value.
- `sigma` the square root of the estimated variance of the random error

$$\hat{\sigma}^2 = \frac{1}{n - p} \sum_i R_i^2,$$

where  $R_i$  is the  $i$ -th weighted residual.

- `df` degrees of freedom, a 2-vector  $(p, n - p)$ . (Here and elsewhere  $n$  omits observations with zero weights.)
- `cov.unscaled` a  $p \times p$  matrix of (unscaled) covariances of the parameter estimates.
- `correlation` the correlation matrix corresponding to the above `cov.unscaled`, if `correlation = TRUE` is specified and there are a non-zero number of residual degrees of freedom.
- `symbolic.cor` (only if `correlation` is true.) The value of the argument `symbolic.cor`.

See Also

The model fitting function `nls`, `summary`.  
Function `coef` will extract the matrix of coefficients with standard errors, t-statistics and p-values.

|--------|---------------------------------|
| supsmu | <i>Friedman's SuperSmoother</i> |
|--------|---------------------------------|

---

Description

Smooth the (x, y) values by Friedman's 'super smoother'.

Usage

```
supsmu(x, y, wt, span = "cv", periodic = FALSE, bass = 0)
```

Arguments

|          |                                                                                                                                       |
|----------|---------------------------------------------------------------------------------------------------------------------------------------|
| x        | x values for smoothing                                                                                                                |
| y        | y values for smoothing                                                                                                                |
| wt       | case weights, by default all equal                                                                                                    |
| span     | the fraction of the observations in the span of the running lines smoother, or "cv" to choose this by leave-one-out cross-validation. |
| periodic | if TRUE, the x values are assumed to be in [0, 1] and of period 1.                                                                    |
| bass     | controls the smoothness of the fitted curve. Values of up to 10 indicate increasing smoothness.                                       |

## Details

supsmu is a running lines smoother which chooses between three spans for the lines. The running lines smoothers are symmetric, with  $k/2$  data points each side of the predicted point, and values of  $k$  as  $0.5 * n$ ,  $0.2 * n$  and  $0.05 * n$ , where  $n$  is the number of data points. If span is specified, a single smoother with span  $span * n$  is used.

The best of the three smoothers is chosen by cross-validation for each prediction. The best spans are then smoothed by a running lines smoother and the final prediction chosen by linear interpolation.

The FORTRAN code says: “For small samples ( $n < 40$ ) or if there are substantial serial correlations between observations close in x-value, then a pre-specified fixed span smoother ( $span > 0$ ) should be used. Reasonable span values are 0.2 to 0.4.”

Cases with non-finite values of  $x$ ,  $y$  or  $wt$  are dropped, with a warning.

## Value

A list with components

|     |                                                               |
|-----|---------------------------------------------------------------|
| $x$ | the input values in increasing order with duplicates removed. |
| $y$ | the corresponding $y$ values on the fitted curve.             |

|               |                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x             | numeric or logical vector or array.                                                                                                                                                                                                                                                                                                                                                                    |
| cutpoints     | numeric vector whose values $\text{cutpoints}[j] = c_j$ ( <i>after</i> augmentation, see <code>corr</code> below) are used for intervals.                                                                                                                                                                                                                                                              |
| symbols       | character vector, one shorter than (the <i>augmented</i> , see <code>corr</code> below) <code>cutpoints</code> . $\text{symbols}[j] = s_j$ are used as ‘code’ for the (half open) interval $(c_j, c_{j+1}]$ .<br>When <code>numeric.x</code> is FALSE, i.e., by default when argument <code>x</code> is logical, the default is <code>c(".", " ")</code> (graphical 0 / 1 s).                          |
| legend        | logical indicating if a “legend” attribute is desired.                                                                                                                                                                                                                                                                                                                                                 |
| na            | character or logical. How NAs are coded. If <code>na == FALSE</code> , NAs are coded invisibly, <i>including</i> the “legend” attribute below, which otherwise mentions NA coding.                                                                                                                                                                                                                     |
| eps           | absolute precision to be used at left and right boundary.                                                                                                                                                                                                                                                                                                                                              |
| numeric.x     | logical indicating if <code>x</code> should be treated as numbers, otherwise as logical.                                                                                                                                                                                                                                                                                                               |
| corr          | logical. If TRUE, <code>x</code> contains correlations. The cutpoints are augmented by 0 and 1 and <code>abs(x)</code> is coded.                                                                                                                                                                                                                                                                       |
| show.max      | if TRUE, or of mode character, the maximal cutpoint is coded especially.                                                                                                                                                                                                                                                                                                                               |
| show.min      | if TRUE, or of mode character, the minimal cutpoint is coded especially.                                                                                                                                                                                                                                                                                                                               |
| abbr.colnames | logical, integer or NULL indicating how column names should be abbreviated (if they are); if NULL (or FALSE and <code>x</code> has no column names), the column names will all be empty, i.e., “”; otherwise if <code>abbr.colnames</code> is false, they are left unchanged. If TRUE or integer, existing column names will be abbreviated to <code>abbreviate(*, minlength = abbr.colnames)</code> . |

`lower.triangular` logical. If TRUE and `x` is a matrix, only the *lower triangular* part of the matrix is coded as non-blank.

`diag.lower.tri` logical. If `lower.triangular` *and* this are TRUE, the *diagonal* part of the matrix is shown.

### Value

An atomic character object of class `noquote` and the same dimensions as `x`.

If `legend` is TRUE (as by default when there are more than two classes), the result has an attribute "legend" containing a legend of the returned character codes, in the form

$$c_1 s_1 c_2 s_2 \dots s_n c_{n+1}$$

where  $c_j$  = `cutpoints[j]` and  $s_j$  = `symbols[j]`.

### Note

The optional (mostly logical) arguments all try to use smart defaults. Specifying them explicitly may lead to considerably improved output in many cases.

t.test

*Student's t-Test*

---

## Description

Performs one and two sample t-tests on vectors of data.

## Usage

```

t.test(x, ...)

## Default S3 method:
t.test(x, y = NULL,
       alternative = c("two.sided", "less", "greater"),
       mu = 0, paired = FALSE, var.equal = FALSE,
       conf.level = 0.95, ...)

## S3 method for class 'formula'
t.test(formula, data, subset, na.action, ...)

```

## Arguments

|             |                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | a (non-empty) numeric vector of data values.                                                                                                                  |
| y           | an optional (non-empty) numeric vector of data values.                                                                                                        |
| alternative | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. |
| mu          | a number indicating the true value of the mean (or difference in means if you are performing a two sample test).                                              |
| paired      | a logical indicating whether you want a paired t-test.                                                                                                        |

|                         |                                                                                                                                                                                                                                            |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>var.equal</code>  | a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used. |
| <code>conf.level</code> | confidence level of the interval.                                                                                                                                                                                                          |
| <code>formula</code>    | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> a factor with two levels giving the corresponding groups.                                            |
| <code>data</code>       | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .                 |
| <code>subset</code>     | an optional vector specifying a subset of observations to be used.                                                                                                                                                                         |
| <code>na.action</code>  | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                                 |
| <code>...</code>        | further arguments to be passed to or from methods.                                                                                                                                                                                         |

### Details

The formula interface is only applicable for the 2-sample tests.

`alternative = "greater"` is the alternative that `x` has a larger mean than `y`.

If `paired` is TRUE then both `x` and `y` must be specified and they must be the same length. Missing values are silently removed (in pairs if `paired` is TRUE). If `var.equal` is TRUE then the pooled estimate of the variance is used. By default, if `var.equal` is FALSE then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.

If the input data are effectively constant (compared to the larger of the two means) an error is generated.

### Value

A list with class `"htest"` containing the following components:

|                          |                                                                                                                                     |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>statistic</code>   | the value of the t-statistic.                                                                                                       |
| <code>parameter</code>   | the degrees of freedom for the t-statistic.                                                                                         |
| <code>p.value</code>     | the p-value for the test.                                                                                                           |
| <code>conf.int</code>    | a confidence interval for the mean appropriate to the specified alternative hypothesis.                                             |
| <code>estimate</code>    | the estimated mean or difference in means depending on whether it was a one-sample test or a two-sample test.                       |
| <code>null.value</code>  | the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test. |
| <code>alternative</code> | a character string describing the alternative hypothesis.                                                                           |
| <code>method</code>      | a character string indicating what type of t-test was performed.                                                                    |
| <code>data.name</code>   | a character string giving the name(s) of the data.                                                                                  |

**Examples**

```
require(graphics)

t.test(1:10, y = c(7:20))      # P = .00001855
t.test(1:10, y = c(7:20, 200)) # P = .1245    -- NOT significant anymore

## Classical example: Student's sleep data
plot(extra ~ group, data = sleep)
## Traditional interface
with(sleep, t.test(extra[group == 1], extra[group == 2]))
## Formula interface
t.test(extra ~ group, data = sleep)
```

TDist

*The Student t Distribution***Description**

Density, distribution function, quantile function and random generation for the t distribution with df degrees of freedom (and optional non-centrality parameter ncp).

**Usage**

```
dt(x, df, ncp, log = FALSE)
pt(q, df, ncp, lower.tail = TRUE, log.p = FALSE)
qt(p, df, ncp, lower.tail = TRUE, log.p = FALSE)
rt(n, df, ncp)
```

**Arguments**

|            |                                                                                                                                        |
|------------|----------------------------------------------------------------------------------------------------------------------------------------|
| x, q       | vector of quantiles.                                                                                                                   |
| p          | vector of probabilities.                                                                                                               |
| n          | number of observations. If length(n) > 1, the length is taken to be the number required.                                               |
| df         | degrees of freedom (> 0, maybe non-integer). df = Inf is allowed.                                                                      |
| ncp        | non-centrality parameter $\delta$ ; currently except for rt(), only for abs(ncp) <= 37.62. If omitted, use the central t distribution. |
| log, log.p | logical; if TRUE, probabilities p are given as log(p).                                                                                 |
| lower.tail | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                                                  |

**Details**

The  $t$  distribution with  $df = \nu$  degrees of freedom has density

$$f(x) = \frac{\Gamma((\nu + 1)/2)}{\sqrt{\pi\nu}\Gamma(\nu/2)} (1 + x^2/\nu)^{-(\nu+1)/2}$$

for all real  $x$ . It has mean 0 (for  $\nu > 1$ ) and variance  $\frac{\nu}{\nu-2}$  (for  $\nu > 2$ ).

The general *non-central t* with parameters  $(\nu, \delta) = (\text{df}, \text{ncp})$  is defined as the distribution of  $T_\nu(\delta) := (U + \delta)/\sqrt{V/\nu}$  where  $U$  and  $V$  are independent random variables,  $U \sim \mathcal{N}(0, 1)$  and  $V \sim \chi_\nu^2$  (see [Chisquare](#)).

The most used applications are power calculations for  $t$ -tests:

Let  $T = \frac{\bar{X} - \mu_0}{S/\sqrt{n}}$  where  $\bar{X}$  is the [mean](#) and  $S$  the sample standard deviation ([sd](#)) of  $X_1, X_2, \dots, X_n$  which are i.i.d.  $\mathcal{N}(\mu, \sigma^2)$ . Then  $T$  is distributed as non-central  $t$  with  $\text{df} = n - 1$  degrees of freedom and non-centrality parameter  $\text{ncp} = (\mu - \mu_0)\sqrt{n}/\sigma$ .

## Value

`dt` gives the density, `pt` gives the distribution function, `qt` gives the quantile function, and `rt` generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by `n` for `rt`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

## Note

Supplying `ncp = 0` uses the algorithm for the non-central distribution, which is not the same algorithm used if `ncp` is omitted. This is to give consistent behaviour in extreme cases with values of `ncp` very near zero.

The code for non-zero `ncp` is principally intended to be used for moderate values of `ncp`: it will not be highly accurate, especially in the tails, for large values.

## Source

The central `dt` is computed via an accurate formula provided by Catherine Loader (see the reference in [dbinom](#)).

For the non-central case of `dt`, C code contributed by Claus Ekstrøm based on the relationship (for  $x \neq 0$ ) to the cumulative distribution.

For the central case of `pt`, a normal approximation in the tails, otherwise via [pbeta](#).

For the non-central case of `pt` based on a C translation of

Lenth, R. V. (1989). *Algorithm AS 243* — Cumulative distribution function of the non-central  $t$  distribution, *Applied Statistics* **38**, 185–189.

This computes the lower tail only, so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant.

For central `qt`, a C translation of

Hill, G. W. (1970) Algorithm 396: Student's  $t$ -quantiles. *Communications of the ACM*, **13**(10), 619–620.

altered to take account of

Hill, G. W. (1981) Remark on Algorithm 396, *ACM Transactions on Mathematical Software*, **7**, 250–1.

The non-central case is done by inversion.

## Examples

```
require(graphics)

1 - pt(1:5, df = 1)
qt(.975, df = c(1:10,20,50,100,1000))

tt <- seq(0, 10, len = 21)
ncp <- seq(0, 6, len = 31)
ptn <- outer(tt, ncp, function(t, d) pt(t, df = 3, ncp = d))
t.tit <- "Non-central t - Probabilities"
image(tt, ncp, ptn, zlim = c(0,1), main = t.tit)
persp(tt, ncp, ptn, zlim = 0:1, r = 2, phi = 20, theta = 200, main = t.tit,
       xlab = "t", ylab = "non-centrality parameter",
       zlab = "Pr(T <= t)")

plot(function(x) dt(x, df = 3, ncp = 2), -3, 11, ylim = c(0, 0.32),
     main = "Non-central t - Density", yaxs = "i")
```

---

termplot

---

*Plot Regression Terms*

---

## Description

Plots regression terms against their predictors, optionally with standard errors and partial residuals added.

## Usage

```
termplot(model, data = NULL, envir = environment(formula(model)),
         partial.resid = FALSE, rug = FALSE,
         terms = NULL, se = FALSE,
         xlabs = NULL, ylabs = NULL, main = NULL,
```

```
col.term = 2, lwd.term = 1.5,
col.se = "orange", lty.se = 2, lwd.se = 1,
col.res = "gray", cex = 1, pch = par("pch"),
col.smth = "darkred", lty.smth = 2, span.smth = 2/3,
ask = dev.interactive() && nb.fig < n.tms,
use.factor.levels = TRUE, smooth = NULL, ylim = "common",
plot = TRUE, transform.x = FALSE, ...)
```

## Arguments

|                                                                        |                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model</code>                                                     | fitted model object                                                                                                                                                                                                                                                                                                              |

## Details

The model object must have a predict method that accepts `type = "terms"`, e.g., `glm` in the **stats** package, `coxph` and `survreg` in the **survival** package.

For the `partial.resid = TRUE` option model must have a `residuals` method that accepts `type = "partial"`, which `lm` and `glm` do.

The `data` argument should rarely be needed, but in some cases `termplot` may be unable to reconstruct the original data frame. Using `na.action=na.exclude` makes these problems less likely.

Nothing sensible happens for interaction terms, and they may cause errors.

The `plot = FALSE` option is useful when some special action is needed, e.g. to overlay the results of two different models or to plot confidence bands.

## Value

For `plot = FALSE`, a list with one element for each plot which would have been produced. Each element of the list is a data frame with variables `x`, `y`, and optionally the pointwise standard errors `se`. For continuous predictors `x` will contain the ordered unique values and for a factor it will be a factor containing one instance of each level. The list has attribute `"constant"` copied from the predicted terms object.

Otherwise, the number of terms, invisibly.

## See Also

For (generalized) linear models, `plot.lm` and `predict.glm`.

## Examples

```
require(graphics)

had.splines <- "package:splines" %in% search()
if(!had.splines) rs <- require(splines)
x <- 1:100
z <- factor(rep(LETTERS[1:4], 25))
y <- rnorm(100, sin(x/10)+as.numeric(z))
model <- glm(y ~ ns(x, 6) + z)

par(mfrow = c(2,2)) ## 2 x 2 plots for same model :
termplot(model, main = paste("termplot( ", deparse(model$call)," ...)")
termplot(model, rug = TRUE)
termplot(model, partial.resid = TRUE, se = TRUE, main = TRUE)
termplot(model, partial.resid = TRUE, smooth = panel.smooth, span.smth = 1/4)
if(!had.splines && rs) detach("package:splines")

## requires recommended package MASS
hills.lm <- lm(log(time) ~ log(climb)+log(dist), data = MASS::hills)
termplot(hills.lm, partial.resid = TRUE, smooth = panel.smooth,
         terms = "log(dist)", main = "Original")
termplot(hills.lm, transform.x = TRUE,
         partial.resid = TRUE, smooth = panel.smooth,
         terms = "log(dist)", main = "Transformed")
```

|-------|--------------------|
| terms | <i>Model Terms</i> |
|-------|--------------------|

---

## Description

The function `terms` is a generic function which can be used to extract *terms* objects from various kinds of R data objects.

## Usage

```
terms(x, ...)
```

## Arguments

|                  |                                                    |
|------------------|----------------------------------------------------|
| <code>x</code>   | object used to select a method to dispatch.        |
| <code>...</code> | further arguments passed to or from other methods. |

## Details

There are methods for classes `"aovlist"`, and `"terms"` `"formula"` (see [terms.formula](#)): the default method just extracts the `terms` component of the object, or failing that a `"terms"` attribute (as used by [model.frame](#)).

There are [print](#) and [labels](#) methods for class `"terms"`: the latter prints the term labels (see [terms.object](#)).

## Value

An object of class `c("terms", "formula")` which contains the *terms* representation of a symbolic model. See [terms.object](#) for its structure.

| terms.formula | <i>Construct a terms Object from a Formula</i> |
|---------------|------------------------------------------------|

---

## Description

This function takes a formula and some optional arguments and constructs a terms object. The terms object can then be used to construct a `model.matrix`.

## Usage

```
## S3 method for class 'formula'
terms(x, specials = NULL, abb = NULL, data = NULL, neg.out = TRUE,
      keep.order = FALSE, simplify = FALSE, ...,
      allowDotAsName = FALSE)
```

## Arguments

|                |                                                                                                                                                                                                                                                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x              | a formula.                                                                                                                                                                                                                                                                       |
| specials       | which functions in the formula should be marked as special in the terms object?<br>A character vector or NULL.                                                                                                                                                                   |
| abb            | Not implemented in R.                                                                                                                                                                                                                                                            |
| data           | a data frame from which the meaning of the special symbol . can be inferred. It is unused if there is no . in the formula.                                                                                                                                                       |
| neg.out        | Not implemented in R.                                                                                                                                                                                                                                                            |
| keep.order     | a logical value indicating whether the terms should keep their positions. If FALSE the terms are reordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on. Effects of a given order are kept in the order specified. |
| simplify       | should the formula be expanded and simplified, the pre-1.7.0 behaviour?                                                                                                                                                                                                          |
| ...            | further arguments passed to or from other methods.                                                                                                                                                                                                                               |
| allowDotAsName | normally . in a formula refers to the remaining variables contained in data. Exceptionally, . can be treated as a name for non-standard uses of formulae.                                                                                                                        |

## Details

Not all of the options work in the same way that they do in S and not all are implemented.

## Value

A `terms.object` object is returned. The object itself is the re-ordered (unless `keep.order = TRUE`) formula. In all cases variables within an interaction term in the formula are re-ordered by the ordering of the "variables" attribute, which is the order in which the variables occur in the formula.

terms.object

*Description of Terms Objects***Description**

An object of class `terms` holds information about a model. Usually the model was specified in terms of a `formula` and that formula was used to determine the terms object.

**Value**

The object itself is simply the formula supplied to the call of `terms.formula`. The object has a number of attributes and they are used to construct the model frame:

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| factors     | A matrix of variables by terms showing which variables appear in which terms. The entries are 0 if the variable does not occur in the term, 1 if it does occur and should be coded by contrasts, and 2 if it occurs and should be coded via dummy variables for all levels (as when a lower-order term is missing). Note that variables in main effects always receive 1, even if the intercept is missing (in which case the first one should be coded with dummy variables). If there are no terms other than an intercept and offsets, this is <code>numeric(0)</code> . |
| term.labels | A character vector containing the labels for each of the terms in the model, except for offsets. Note that these are after possible re-ordering of terms. Non-syntactic names will be quoted by backticks: this makes it easier to re-construct the formula from the term labels.                                                                                                                                                                                                                                                                                           |
| variables   | A call to <code>list</code> of the variables in the model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| intercept   | Either 0, indicating no intercept is to be fit, or 1 indicating that an intercept is to be fit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| order       | A vector of the same length as <code>term.labels</code> indicating the order of interaction for each term.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| response    | The index of the variable (in <code>variables</code> ) of the response (the left hand side of the formula). Zero, if there is no response.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| offset      | If the model contains <code>offset</code> terms there is an <code>offset</code> attribute indicating which variable(s) are offsets                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| specials    | If a <code>specials</code> argument was given to <code>terms.formula</code> there is a <code>specials</code> attribute, a pairlist of vectors (one for each specified special function) giving numeric indices of the arguments of the list returned as the <code>variables</code> attribute which contain these special functions.                                                                                                                                                                                                                                         |
| dataClasses | optional. A named character vector giving the classes (as given by <code>.MFclass</code> ) of the variables used in a fit.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| predvars    | optional. An expression to help in computing predictions at new covariate values; see <code>makepredictcall</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

The object has class `c("terms", "formula")`.

**Note**

These objects are different from those found in S. In particular there is no formula attribute: instead the object is itself a formula. (Thus, the mode of a terms object is different.)

Examples of the specials argument can be seen in the [aov](#) and [coxph](#) functions, the latter from package [survival](#).

**See Also**

[terms](#), [formula](#).

**Examples**

```
## use of specials (as used for gam() in packages mgcv and gam)
(tf <- terms(y ~ x + x:z + s(x), specials = "s"))
## Note that the "factors" attribute has variables as row names
## and term labels as column names, both as character vectors.
attr(tf, "specials")    # index 's' variable(s)
rownames(attr(tf, "factors"))[attr(tf, "specials")$s]

## we can keep the order by
terms(y ~ x + x:z + s(x), specials = "s", keep.order = TRUE)
```

---

time

*Sampling Times of Time Series*

---

**Description**

time creates the vector of times at which a time series was sampled.

cycle gives the positions in the cycle of each observation.

frequency returns the number of samples per unit time and deltat the time interval between observations (see [ts](#)).

**Usage**

```
time(x, ...)
## Default S3 method:
time(x, offset = 0, ...)

cycle(x, ...)
frequency(x, ...)
deltat(x, ...)
```

**Arguments**

|        |                                                                                                                                                                   |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | a univariate or multivariate time-series, or a vector or matrix.                                                                                                  |
| offset | can be used to indicate when sampling took place in the time unit. 0 (the default) indicates the start of the unit, 0.5 the middle and 1 the end of the interval. |
| ...    | extra arguments for future methods.                                                                                                                               |

**Details**

These are all generic functions, which will use the `tsp` attribute of `x` if it exists. `time` and `cycle` have methods for class `ts` that coerce the result to that class.

**References**

**See Also**

`ts`, `start`, `tsp`, `window`.

`date` for clock time, `system.time` for CPU usage.

**Examples**

```
require(graphics)

cycle(presidents)
# a simple series plot
plot(as.vector(time(presidents)), as.vector(presidents), type = "l")
```

---

toeplitz

*Form Symmetric Toeplitz Matrix*

---

**Description**

Forms a symmetric Toeplitz matrix given its first row.

**Usage**

```
toeplitz(x, ...)
```

**Arguments**

`x` the first row to form the Toeplitz matrix.  
`...` potential further arguments (for methods); none here.

**Value**

The Toeplitz matrix.

**Author(s)**

A. Trapletti

## Examples

```
x <- 1:5
toeplitz (x)
```

---

ts

*Time-Series Objects*

---

## Description

The function `ts` is used to create time-series objects.

`as.ts` and `is.ts` coerce an object to a time-series and test whether an object is a time series.

## Usage

```
ts(data = NA, start = 1, end = numeric(), frequency = 1,
   deltat = 1, ts.eps = getOption("ts.eps"), class = , names = )
as.ts(x, ...)
is.ts(x)
```

## Arguments

|                        |                                                                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | a vector or matrix of the observed time-series values. A data frame will be coerced to a numeric matrix via <code>data.matrix</code> . (See also ‘Details’.)                                                                    |
| <code>start</code>     | the time of the first observation. Either a single number or a vector of two integers, which specify a natural time unit and a (1-based) number of samples into the time unit. See the examples for the use of the second form. |
| <code>end</code>       | the time of the last observation, specified in the same way as <code>start</code> .                                                                                                                                             |
| <code>frequency</code> | the number of observations per unit of time.                                                                                                                                                                                    |
| <code>deltat</code>    | the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of <code>frequency</code> or <code>deltat</code> should be provided.                                                 |
| <code>ts.eps</code>    | time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than <code>ts.eps</code> .                                                                                              |
| <code>class</code>     | class to be given to the result, or none if <code>NULL</code> or <code>"none"</code> . The default is <code>"ts"</code> for a single series, <code>c("mts", "ts", "matrix")</code> for multiple series.                         |
| <code>names</code>     | a character vector of names for the series in a multiple series: defaults to the <code>colnames</code> of <code>data</code> , or <code>Series 1, Series 2, ...</code> .                                                         |
| <code>x</code>         | an arbitrary R object.                                                                                                                                                                                                          |
| <code>...</code>       | arguments passed to methods (unused for the default method).                                                                                                                                                                    |

## Details

The function `ts` is used to create time-series objects. These are vector or matrices with class of `"ts"` (and additional attributes) which represent data which has been sampled at equispaced points in time. In the matrix case, each column of the matrix data is assumed to contain a single (univariate) time series. Time series must have at least one observation, and although they need not be numeric there is very limited support for non-numeric series.

Class `"ts"` has a number of methods. In particular arithmetic will attempt to align time axes, and subsetting to extract subsets of series can be used (e.g., `EuStockMarkets[, "DAX"]`). However, subsetting the first (or only) dimension will return a matrix or vector, as will matrix subsetting. Subassignment can be used to replace values but not to extend a series (see [window](#)). There is a method for `t` that transposes the series as a matrix (a one-column matrix if a vector) and hence returns a result that does not inherit from class `"ts"`.

The value of argument `frequency` is used when the series is sampled an integral number of times in each unit time interval. For example, one could use a value of 7 for frequency when the data are sampled daily, and the natural time period is a week, or 12 when the data are sampled monthly and the natural time period is a year. Values of 4 and 12 are assumed in (e.g.) print methods to imply a quarterly and monthly series respectively.

`as.ts` is generic. Its default method will use the `tsp` attribute of the object if it has one to set the start and end times and frequency.

`is.ts` tests if an object is a time series. It is generic: you can write methods to handle specific classes of objects, see [InternalMethods](#).

[tsp](#), [frequency](#), [start](#), [end](#), [time](#), [window](#); [print.ts](#), the print method for time series objects; [plot.ts](#), the plot method for time series objects.

For other definitions of ‘time series’ (e.g., time-ordered observations) see the CRAN task view at <https://cran.r-project.org/web/views/TimeSeries.html>.

## Examples

```
require(graphics)

ts(1:10, frequency = 4, start = c(1959, 2)) # 2nd Quarter of 1959
print( ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)
# print.ts(.)
## Using July 1954 as start date:
gnp <- ts(cumsum(1 + round(rnorm(100), 2)),
          start = c(1954, 7), frequency = 12)
plot(gnp) # using 'plot.ts' for time-series plot

## Multivariate
z <- ts(matrix(rnorm(300), 100, 3), start = c(1961, 1), frequency = 12)
```

```
class(z)
head(z) # as "matrix"
plot(z)
plot(z, plot.type = "single", lty = 1:3)

## A phase plot:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
     main = "Lag plot of New Haven temperatures")
```

---

ts-methods

*Methods for Time Series Objects*

---

## Description

Methods for objects of class "ts", typically the result of [ts](#).

## Usage

```
## S3 method for class 'ts'
diff(x, lag = 1, differences = 1, ...)

## S3 method for class 'ts'
na.omit(object, ...)
```

## Arguments

|             |                                                                  |
|-------------|------------------------------------------------------------------|
| x           | an object of class "ts" containing the values to be differenced. |
| lag         | an integer indicating which lag to use.                          |
| differences | an integer indicating the order of the difference.               |
| object      | a univariate or multivariate time series.                        |
| ...         | further arguments to be passed to or from methods.               |

## Details

The `na.omit` method omits initial and final segments with missing values in one or more of the series. 'Internal' missing values will lead to failure.

## Value

For the `na.omit` method, a time series without missing values. The class of object will be preserved.

## See Also

[diff](#); [na.omit](#), [na.fail](#), [na.contiguous](#).

---

`ts.plot`*Plot Multiple Time Series*

---

### Description

Plot several time series on a common plot. Unlike [plot.ts](#) the series can have a different time bases, but they should have the same frequency.

### Usage

```
ts.plot(..., gpars = list())
```

### Arguments

|                    |                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code>   | one or more univariate or multivariate time series.                                                                                        |
| <code>gpars</code> | list of named graphics parameters to be passed to the plotting functions. Those commonly used can be supplied directly in <code>...</code> |

### Value

None.

### Note

Although this can be used for a single time series, `plot` is easier to use and is preferred.

### See Also

[plot.ts](#)

### Examples

```
require(graphics)

ts.plot(ldeaths, mdeaths, fdeaths,
       gpars=list(xlab="year", ylab="deaths", lty=c(1:3)))
```

---

|          |                                     |
|----------|-------------------------------------|
| ts.union | <i>Bind Two or More Time Series</i> |
|----------|-------------------------------------|

---

## Description

Bind time series which have a common frequency. `ts.union` pads with NAs to the total time coverage, `ts.intersect` restricts to the time covered by all the series.

## Usage

```
ts.intersect(..., dframe = FALSE)
ts.union(..., dframe = FALSE)
```

## Arguments

|        |                                                                                                  |
|--------|--------------------------------------------------------------------------------------------------|
| ...    | two or more univariate or multivariate time series, or objects which can coerced to time series. |
| dframe | logical; if TRUE return the result as a data frame.                                              |

## Details

As a special case, ... can contain vectors or matrices of the same length as the combined time series of the time series present, as well as those of a single row.

## Value

A time series object if `dframe` is FALSE, otherwise a data frame.

## See Also

[cbind](#).

## Examples

```
ts.union(mdeaths, fdeaths)
cbind(mdeaths, fdeaths) # same as the previous line
ts.intersect(window(mdeaths, 1976), window(fdeaths, 1974, 1978))

sales1 <- ts.union(BJsales, lead = BJsales.lead)
ts.intersect(sales1, lead3 = lag(BJsales.lead, -3))
```

---

tsdiag*Diagnostic Plots for Time-Series Fits*

---

**Description**

A generic function to plot time-series diagnostics.

**Usage**

```
tsdiag(object, gof.lag, ...)
```

**Arguments**

|                      |                                                                   |
|----------------------|-------------------------------------------------------------------|
| <code>object</code>  | a fitted time-series model                                        |
| <code>gof.lag</code> | the maximum number of lags for a Portmanteau goodness-of-fit test |
| <code>...</code>     | further arguments to be passed to particular methods              |

**Details**

This is a generic function. It will generally plot the residuals, often standardized, the autocorrelation function of the residuals, and the p-values of a Portmanteau test for all lags up to `gof.lag`.

The methods for [arima](#) and [StructTS](#) objects plots residuals scaled by the estimate of their (individual) variance, and use the Ljung–Box version of the portmanteau test.

**Value**

None. Diagnostics are plotted.

**See Also**

[arima](#), [StructTS](#), [Box.test](#)

**Examples**

```
require(graphics)

fit <- arima(lh, c(1,0,0))
tsdiag(fit)

## see also examples(arima)

(fit <- StructTS(log10(JohnsonJohnson), type = "BSM"))
tsdiag(fit)
```

---

tsp*Tsp Attribute of Time-Series-like Objects*

---

### Description

tsp returns the tsp attribute (or NULL). It is included for compatibility with S version 2. `tsp<-` sets the tsp attribute. `hasTsp` ensures x has a tsp attribute, by adding one if needed.

### Usage

```
tsp(x)
tsp(x) <- value
hasTsp(x)
```

### Arguments

|       |                                                               |
|-------|---------------------------------------------------------------|
| x     | a vector or matrix or univariate or multivariate time-series. |
| value | a numeric vector of length 3 or NULL.                         |

### Details

The tsp attribute gives the start time *in time units*, the end time and the frequency (the number of observations per unit of time, e.g. 12 for a monthly series).

Assignments are checked for consistency.

Assigning NULL which removes the tsp attribute *and* any "ts" (or "mts") class of x.

### Value

An object which differs from x only in the tsp attribute (unless NULL is assigned).

`hasTsp` adds, if needed, an attribute with a start time and frequency of 1 and end time `NROW(x)`.

---

tsSmooth*Use Fixed-Interval Smoothing on Time Series*

---

### Description

Performs fixed-interval smoothing on a univariate time series via a state-space model. Fixed-interval smoothing gives the best estimate of the state at each time point based on the whole observed series.

### Usage

```
tsSmooth(object, ...)
```

### Arguments

|        |                                                                                   |
|--------|-----------------------------------------------------------------------------------|
| object | a time-series fit. Currently only class " <a href="#">StructTS</a> " is supported |
| ...    | possible arguments for future methods.                                            |

### Value

A time series, with as many dimensions as the state space and results at each time point of the original series. (For seasonal models, only the current seasonal component is returned.)

### Author(s)

B. D. Ripley

### References

## Description

Functions of the distribution of the studentized range,  $R/s$ , where  $R$  is the range of a standard normal sample and  $df \times s^2$  is independently distributed as chi-squared with  $df$  degrees of freedom, see [pchisq](#).

## Usage

```
ptukey(q, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
qtukey(p, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
```

## Arguments

|                         |                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------|
| <code>q</code>          | vector of quantiles.                                                                  |
| <code>p</code>          | vector of probabilities.                                                              |
| <code>nmeans</code>     | sample size for range (same for each group).                                          |
| <code>df</code>         | degrees of freedom for $s$ (see below).                                               |
| <code>nranges</code>    | number of <i>groups</i> whose <b>maximum</b> range is considered.                     |
| <code>log.p</code>      | logical; if TRUE, probabilities $p$ are given as $\log(p)$ .                          |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ . |

## Details

If  $n_g = \text{nranges}$  is greater than one,  $R$  is the *maximum* of  $n_g$  groups of  $n\text{means}$  observations each.

## Value

`ptukey` gives the distribution function and `qtukey` its inverse, the quantile function.

The length of the result is the maximum of the lengths of the numerical arguments. The other numerical arguments are recycled to that length. Only the first elements of the logical arguments are used.

## Note

A Legendre 16-point formula is used for the integral of `ptukey`. The computations are relatively expensive, especially for `qtukey` which uses a simple secant method for finding the inverse of `ptukey`. `qtukey` will be accurate to the 4th decimal place.

## Source

`qtukey` is in part adapted from Odeh and Evans (1974).

Examples

```
if(interactive())
  curve(ptukey(x, nm = 6, df = 5), from = -1, to = 8, n = 101)
(ptt <- ptukey(0:10, 2, df = 5))
(qtt <- qtukey(.95, 2, df = 2:11))
## The precision may be not much more than about 8 digits:
summary(abs(.95 - ptukey(qtt, 2, df = 2:11)))
```

---

|          |                                                     |
|----------|-----------------------------------------------------|
| TukeyHSD | <i>Compute Tukey Honest Significant Differences</i> |
|----------|-----------------------------------------------------|

---

Description

Create a set of confidence intervals on the differences between the means of the levels of a factor with the specified family-wise probability of coverage. The intervals are based on the Studentized range statistic, Tukey’s ‘Honest Significant Difference’ method.

Usage

```
TukeyHSD(x, which, ordered = FALSE, conf.level = 0.95, ...)
```

Arguments

|            |                                                                                                                                                                                                                                                                                                                            |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x          | A fitted model object, usually an <a href="#">aov</a> fit.                                                                                                                                                                                                                                                                 |
| which      | A character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.                                                                                                                                                                                              |
| ordered    | A logical value indicating if the levels of the factor should be ordered according to increasing average in the sample before taking differences. If ordered is true then the calculated differences in the means will all be positive. The significant differences will be those for which the lwr end point is positive. |
| conf.level | A numeric value between zero and one giving the family-wise confidence level to use.                                                                                                                                                                                                                                       |
| ...        | Optional additional arguments. None are used at present.                                                                                                                                                                                                                                                                   |

## Details

This is a generic function: the description here applies to the method for fits of class "aov".

When comparing the means for the levels of a factor in an analysis of variance, a simple comparison using t-tests will inflate the probability of declaring a significant difference when it is not in fact present. This because the intervals are calculated with a given coverage probability for each interval but the interpretation of the coverage is usually with respect to the entire family of intervals.

John Tukey introduced intervals based on the range of the sample means rather than the individual differences. The intervals returned by this function are based on this Studentized range statistics.

The intervals constructed in this way would only apply exactly to balanced designs where there are the same number of observations made at each level of the factor. This function incorporates an adjustment for sample size that produces sensible intervals for mildly unbalanced designs.

If which specifies non-factor terms these will be dropped with a warning: if no terms are left this is an error.

## Value

A list of class `c("multicomp", "TukeyHSD")`, with one component for each term requested in which. Each component is a matrix with columns `diff` giving the difference in the observed means, `lwr` giving the lower end point of the interval, `upr` giving the upper end point and `p.adj` giving the p-value after adjustment for the multiple comparisons.

There are print and plot methods for class "TukeyHSD". The plot method does not accept `xlab`, `ylab` or `main` arguments and creates its own values for each plot.

## Examples

```
require(graphics)

summary(fm1 <- aov(breaks ~ wool + tension, data = warpbreaks))
TukeyHSD(fm1, "tension", ordered = TRUE)
plot(TukeyHSD(fm1, "tension"))
```

## Uniform

*The Uniform Distribution***Description**

These functions provide information about the uniform distribution on the interval from min to max. dunif gives the density, punif gives the distribution function qunif gives the quantile function and runif generates random deviates.

**Usage**

```
dunif(x, min = 0, max = 1, log = FALSE)
punif(q, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
qunif(p, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
runif(n, min = 0, max = 1)
```

**Arguments**

|            |                                                                                          |
|------------|------------------------------------------------------------------------------------------|
| x, q       | vector of quantiles.                                                                     |
| p          | vector of probabilities.                                                                 |
| n          | number of observations. If length(n) > 1, the length is taken to be the number required. |
| min, max   | lower and upper limits of the distribution. Must be finite.                              |
| log, log.p | logical; if TRUE, probabilities p are given as log(p).                                   |
| lower.tail | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .    |

**Details**

If min or max are not specified they assume the default values of 0 and 1 respectively.

The uniform distribution has density

$$f(x) = \frac{1}{\max - \min}$$

for  $\min \leq x \leq \max$ .

For the case of  $u := \min == \max$ , the limit case of  $X \equiv u$  is assumed, although there is no density in that case and dunif will return NaN (the error condition).

runif will not generate either of the extreme values unless  $\max = \min$  or  $\max - \min$  is small compared to min, and in particular not for the default arguments.

**Value**

dunif gives the density, punif gives the distribution function, qunif gives the quantile function, and runif generates random deviates.

The length of the result is determined by n for runif, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

The characteristics of output from pseudo-random number generators (such as precision and periodicity) vary widely. See [.Random.seed](#) for more information on R's random number generation algorithms.

**References**

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

**See Also**

[RNG](#) about random number generation in R.

[Distributions](#) for other standard distributions.

**Examples**

```
u <- runif(20)

## The following relations always hold :
punif(u) == u
dunif(u) == 1

var(runif(10000)) #- ~ = 1/12 = .08333
```

---

uniroot

---

*One Dimensional Root (Zero) Finding*

---

**Description**

The function `uniroot` searches the interval from `lower` to `upper` for a root (i.e., zero) of the function `f` with respect to its first argument.

Setting `extendInt` to a non-"no" string, means searching for the correct interval = `c(lower,upper)` if `sign(f(x))` does not satisfy the requirements at the interval end points; see the 'Details' section.

**Usage**

```
uniroot(f, interval, ...,
        lower = min(interval), upper = max(interval),
        f.lower = f(lower, ...), f.upper = f(upper, ...),
        extendInt = c("no", "yes", "downX", "upX"), check.conv = FALSE,
        tol = .Machine$double.eps^0.25, maxiter = 1000, trace = 0)
```

## Arguments

|                               |                                                                                                                                                                                                                                                                                               |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>                | the function for which the root is sought.                                                                                                                                                                                                                                                    |
| <code>interval</code>         | a vector containing the end-points of the interval to be searched for the root.                                                                                                                                                                                                               |
| <code>...</code>              | additional named or unnamed arguments to be passed to <code>f</code>                                                                                                                                                                                                                          |
| <code>lower, upper</code>     | the lower and upper end points of the interval to be searched.                                                                                                                                                                                                                                |
| <code>f.lower, f.upper</code> | the same as <code>f(upper)</code> and <code>f(lower)</code> , respectively. Passing these values from the caller where they are often known is more economical as soon as <code>f()</code> contains non-trivial computations.                                                                 |
| <code>extendInt</code>        | character string specifying if the interval <code>c(lower, upper)</code> should be extended or directly produce an error when <code>f()</code> does not have differing signs at the end-points. The default, "no", keeps the search interval and hence produces an error. Can be abbreviated. |
| <code>check.conv</code>       | logical indicating whether a convergence warning of the underlying <code>uniroot</code> should be caught as an error and if non-convergence in <code>maxiter</code> iterations should be an error instead of a warning.                                                                       |
| <code>tol</code>              | the desired accuracy (convergence tolerance).                                                                                                                                                                                                                                                 |
| <code>maxiter</code>          | the maximum number of iterations.                                                                                                                                                                                                                                                             |
| <code>trace</code>            | integer number; if positive, tracing information is produced. Higher values giving more details.                                                                                                                                                                                              |

## Details

Note that arguments after `...` must be matched exactly.

Either `interval` or both `lower` and `upper` must be specified: the upper endpoint must be strictly larger than the lower endpoint. The function values at the endpoints must be of opposite signs (or zero), for `extendInt="no"`, the default. Otherwise, if `extendInt="yes"`, the interval is extended on both sides, in search of a sign change, i.e., until the search interval  $[l, u]$  satisfies  $f(l) \cdot f(u) \leq 0$ .

If it is *known how*  $f$  changes sign at the root  $x_0$ , that is, if the function is increasing or decreasing there, `extendInt` can (and typically should) be specified as "upX" (for "upward crossing") or "downX", respectively. Equivalently, define  $S := \pm 1$ , to require  $S = \text{sign}(f(x_0 + \epsilon))$  at the solution. In that case, the search interval  $[l, u]$  possibly is extended to be such that  $S \cdot f(l) \leq 0$  and  $S \cdot f(u) \geq 0$ .

`uniroot()` uses Fortran subroutine "zeroin" (from Netlib) based on algorithms given in the reference below. They assume a continuous function (which then is known to have at least one root in the interval).

Convergence is declared either if  $f(x) == 0$  or the change in  $x$  for one step of the algorithm is less than `tol` (plus an allowance for representation error in  $x$ ).

If the algorithm does not converge in `maxiter` steps, a warning is printed and the current approximation is returned.

`f` will be called as `f(x, ...)` for a numeric value of  $x$ .

The argument passed to `f` has special semantics and used to be shared between calls. The function should not copy it.

**Value**

A list with at least four components: `root` and `f.root` give the location of the root and the value of the function evaluated at that point. `iter` and `estim.prec` give the number of iterations used and an approximate estimated precision for root. (If the root occurs at one of the endpoints, the estimated precision is NA.)

Further components may be added in future: component `init.it` was added in R 3.1.0.

**Source**

Based on 'zeroin.c' in <http://www.netlib.org/c/brent.shar>.

**References**

**See Also**

[polyroot](#) for all complex roots of a polynomial; [optimize](#), [nlm](#).

**Examples**

```
require(utils) # for str

## some platforms hit zero exactly on the first step:
## if so the estimated precision is 2/3.
f <- function(x, a) x - a
str(xmin <- uniroot(f, c(0, 1), tol = 0.0001, a = 1/3))

## handheld calculator example: fixed point of cos(.):
uniroot(function(x) cos(x) - x, lower = -pi, upper = pi, tol = 1e-9)$root

str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
             tol = 0.0001))
str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
             tol = 1e-10))

## Find the smallest value x for which exp(x) > 0 (numerically):
r <- uniroot(function(x) 1e80*exp(x) - 1e-300, c(-1000, 0), tol = 1e-15)
str(r, digits.d = 15) # around -745, depending on the platform.

exp(r$root)      # = 0, but not for r$root * 0.999...
minexp <- r$root * (1 - 10*.Machine$double.eps)
exp(minexp)      # typically denormalized

##--- uniroot() with new interval extension + checking features: -----
f1 <- function(x) (121 - x^2)/(x^2+1)
f2 <- function(x) exp(-x)*(x - 12)
```

```

try(uniroot(f1, c(0,10)))
try(uniroot(f2, c(0, 2)))
##--> error: f() .. end points not of opposite sign

## where as 'extendInt="yes"' simply first enlarges the search interval:
u1 <- uniroot(f1, c(0,10),extendInt="yes", trace=1)
u2 <- uniroot(f2, c(0,2), extendInt="yes", trace=2)
stopifnot(all.equal(u1$root, 11, tolerance = 1e-5),
          all.equal(u2$root, 12, tolerance = 6e-6))

## The *danger* of interval extension:
## No way to find a zero of a positive function, but
## numerically,  $f(-|M|)$  becomes zero :
u3 <- uniroot(exp, c(0,2), extendInt="yes", trace=TRUE)

## Nonsense example (must give an error):
tools::assertCondition( uniroot(function(x) 1, 0:1, extendInt="yes"),
                        "error", verbose=TRUE)

## Convergence checking :
sinc <- function(x) ifelse(x == 0, 1, sin(x)/x)
curve(sinc, -6,18); abline(h=0,v=0, lty=3, col=adjustcolor("gray", 0.8))

uniroot(sinc, c(0,5), extendInt="yes", maxiter=4) #-> "just" a warning

## now with check.conv=TRUE, must signal a convergence error :

uniroot(sinc, c(0,5), extendInt="yes", maxiter=4, check.conv=TRUE)

### Weibull cumulative hazard (example origin, Ravi Varadhan):
cumhaz <- function(t, a, b) b * (t/b)^a
froot <- function(x, u, a, b) cumhaz(x, a, b) - u

n <- 1000
u <- -log(runif(n))
a <- 1/2
b <- 1
## Find failure times
ru <- sapply(u, function(x)
  uniroot(froot, u=x, a=a, b=b, interval= c(1.e-14, 1e04),
    extendInt="yes")$root)
ru2 <- sapply(u, function(x)
  uniroot(froot, u=x, a=a, b=b, interval= c(0.01, 10),
    extendInt="yes")$root)
stopifnot(all.equal(ru, ru2, tolerance = 6e-6))

r1 <- uniroot(froot, u= 0.99, a=a, b=b, interval= c(0.01, 10),
  extendInt="up")
stopifnot(all.equal(0.99, cumhaz(r1$root, a=a, b=b)))

```

```
## An error if 'extendInt' assumes "wrong zero-crossing direction":
uniroot(froot, u= 0.99, a=a, b=b, interval= c(0.1, 10), extendInt="down")
```

---

update

---

*Update and Re-fit a Model Call*

---

## Description

update will update and (by default) re-fit a model. It does this by extracting the call stored in the object, updating the call and (by default) evaluating that call. Sometimes it is useful to call update with only one argument, for example if the data frame has been corrected.

“Extracting the call” in update() and similar functions uses getCall() which itself is a (S3) generic function with a default method that simply gets x\$call.

Because of this, update() will often work (via its default method) on new model classes, either automatically, or by providing a simple getCall() method for that class.

## Usage

```
update(object, ...)
## Default S3 method:
update(object, formula., ..., evaluate = TRUE)

getCall(x, ...)
```

## Arguments

|           |                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------|
| object, x | An existing fit from a model function such as lm, glm and many others.                                           |
| formula.  | Changes to the formula – see update.formula for details.                                                         |
| ...       | Additional arguments to the call, or arguments with changed values. Use name = NULL to remove the argument name. |
| evaluate  | If true evaluate the new call else return the call.                                                              |

## Value

If evaluate = TRUE the fitted object, otherwise the updated call.

|----------------|-----------------------|
| update.formula | <i>Model Updating</i> |
|----------------|-----------------------|

---

## Description

update.formula is used to update model formulae. This typically involves adding or dropping terms, but updates can be more general.

## Usage

```
## S3 method for class 'formula'
update(old, new, ...)
```

## Arguments

|     |                                                            |
|-----|------------------------------------------------------------|
| old | a model formula to be updated.                             |
| new | a formula giving a template which specifies how to update. |
| ... | further arguments passed to or from other methods.         |

## Details

Either or both of old and new can be objects such as length-one character vectors which can be coerced to a formula via [as.formula](#).

The function works by first identifying the *left-hand side* and *right-hand side* of the old formula. It then examines the new formula and substitutes the *lhs* of the old formula for any occurrence of ‘.’ on the left of new, and substitutes the *rhs* of the old formula for any occurrence of ‘.’ on the right of new. The result is then simplified via [terms.formula](#)(simplify = TRUE).

## Value

The updated formula is returned. The environment of the result is that of old.

**See Also**

[terms, model.matrix.](#)

**Examples**

```
update(y ~ x,      ~ . + x2) #> y ~ x + x2
update(y ~ x, log(.) ~ . ) #> log(y) ~ x
update(. ~ u+v, res ~ . ) #> res ~ u + v
```

---

var.test

*F Test to Compare Two Variances*

---

**Description**

Performs an F test to compare the variances of two samples from normal populations.

**Usage**

```
var.test(x, ...)

## Default S3 method:
var.test(x, y, ratio = 1,
         alternative = c("two.sided", "less", "greater"),
         conf.level = 0.95, ...)

## S3 method for class 'formula'
var.test(formula, data, subset, na.action, ...)
```

**Arguments**

|             |                                                                                                                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x, y        | numeric vectors of data values, or fitted linear model objects (inheriting from class "lm").                                                                                                   |
| ratio       | the hypothesized ratio of the population variances of x and y.                                                                                                                                 |
| alternative | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.                                  |
| conf.level  | confidence level for the returned confidence interval.                                                                                                                                         |
| formula     | a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.                                       |
| data        | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula formula. By default the variables are taken from environment(formula). |
| subset      | an optional vector specifying a subset of observations to be used.                                                                                                                             |
| na.action   | a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").                                                                                   |
| ...         | further arguments to be passed to or from methods.                                                                                                                                             |

## Details

The null hypothesis is that the ratio of the variances of the populations from which  $x$  and  $y$  were drawn, or in the data to which the linear models  $x$  and  $y$  were fitted, is equal to `ratio`.

## Value

A list with class "htest" containing the following components:

|                          |                                                                         |
|--------------------------|-------------------------------------------------------------------------|
| <code>statistic</code>   | the value of the F test statistic.                                      |
| <code>parameter</code>   | the degrees of the freedom of the F distribution of the test statistic. |
| <code>p.value</code>     | the p-value of the test.                                                |
| <code>conf.int</code>    | a confidence interval for the ratio of the population variances.        |
| <code>estimate</code>    | the ratio of the sample variances of $x$ and $y$ .                      |
| <code>null.value</code>  | the ratio of population variances under the null.                       |
| <code>alternative</code> | a character string describing the alternative hypothesis.               |
| <code>method</code>      | the character string "F test to compare two variances".                 |
| <code>data.name</code>   | a character string giving the names of the data.                        |

## See Also

[bartlett.test](#) for testing homogeneity of variances in more than two samples from normal distributions; [ansari.test](#) and [mood.test](#) for two rank based (nonparametric) two-sample tests for difference in scale.

## Examples

```
x <- rnorm(50, mean = 0, sd = 2)
y <- rnorm(30, mean = 1, sd = 1)
var.test(x, y)           # Do x and y have the same variance?
var.test(lm(x ~ 1), lm(y ~ 1)) # The same.
```

---

varimax

*Rotation Methods for Factor Analysis*

---

## Description

These functions 'rotate' loading matrices in factor analysis.

## Usage

```
varimax(x, normalize = TRUE, eps = 1e-5)
promax(x, m = 4)
```

## Arguments

|                        |                                                                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | A loadings matrix, with $p$ rows and $k < p$ columns                                                                                                          |
| <code>m</code>         | The power used the target for promax. Values of 2 to 4 are recommended.                                                                                       |
| <code>normalize</code> | logical. Should Kaiser normalization be performed? If so the rows of <code>x</code> are re-scaled to unit length before rotation, and scaled back afterwards. |
| <code>eps</code>       | The tolerance for stopping: the relative change in the sum of singular values.                                                                                |

## Details

These seek a ‘rotation’ of the factors `x %*% T` that aims to clarify the structure of the loadings matrix. The matrix `T` is a rotation (possibly with reflection) for `varimax`, but a general linear transformation for `promax`, with the variance of the factors being preserved.

## Value

A list with components

|                       |                                                                                 |
|-----------------------|---------------------------------------------------------------------------------|
| <code>loadings</code> | The ‘rotated’ loadings matrix, <code>x %*% rotmat</code> , of class “loadings”. |
| <code>rotmat</code>   | The ‘rotation’ matrix.                                                          |

fa <- factanal( ~., 2, data = swiss)
varimax(loadings(fa), normalize = FALSE)
promax(loadings(fa))
```

vcov

*Calculate Variance-Covariance Matrix for a Fitted Model Object***Description**

Returns the variance-covariance matrix of the main parameters of a fitted model object.

**Usage**

```
vcov(object, ...)
```

**Arguments**

**object** a fitted model object, typically. Sometimes also a `summary()` object of such a fitted model.

**...** additional arguments for method functions. For the `glm` method this can be used to pass a dispersion parameter.

**Details**

This is a generic function. Functions with names beginning in `vcov.` will be methods for this function. Classes with methods for this function include: `lm`, `mlm`, `glm`, `nls`, `summary.lm`, `summary.glm`, `negbin`, `polr`, `r1m` (in package **MASS**), `multinom` (in package **nnet**) `gls`, `lme` (in package **nlme**), `coxph` and `survreg` (in package **survival**).

(`vcov()` methods for summary objects allow more efficient and still encapsulated access when both `summary(mod)` and `vcov(mod)` are needed.)

**Value**

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model. This should have row and column names corresponding to the parameter names given by the `coef` method.

Weibull

*The Weibull Distribution***Description**

Density, distribution function, quantile function and random generation for the Weibull distribution with parameters shape and scale.

**Usage**

```
dweibull(x, shape, scale = 1, log = FALSE)
pweibull(q, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
qweibull(p, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
rweibull(n, shape, scale = 1)
```

**Arguments**

|                           |                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>         | vector of quantiles.                                                                                      |
| <code>p</code>            | vector of probabilities.                                                                                  |
| <code>n</code>            | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>shape, scale</code> | shape and scale parameters, the latter defaulting to 1.                                                   |
| <code>log, log.p</code>   | logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .                         |
| <code>lower.tail</code>   | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

**Details**

The Weibull distribution with shape parameter  $a$  and scale parameter  $\sigma$  has density given by

$$f(x) = (a/\sigma)(x/\sigma)^{a-1} \exp(-(x/\sigma)^a)$$

for  $x > 0$ . The cumulative distribution function is  $F(x) = 1 - \exp(-(x/\sigma)^a)$  on  $x > 0$ , the mean is  $E(X) = \sigma\Gamma(1 + 1/a)$ , and the  $Var(X) = \sigma^2(\Gamma(1 + 2/a) - (\Gamma(1 + 1/a))^2)$ .

**Value**

`dweibull` gives the density, `pweibull` gives the distribution function, `qweibull` gives the quantile function, and `rweibull` generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by `n` for `rweibull`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

The cumulative hazard  $H(t) = -\log(1 - F(t))$  is

`-pweibull(t, a, b, lower = FALSE, log = TRUE)`

which is just  $H(t) = (t/b)^a$ .

**Source**

`[dpq]weibull` are calculated directly from the definitions. `rweibull` uses inversion.

## Examples

```
x <- c(0, rlnorm(50))
all.equal(dweibull(x, shape = 1), dexp(x))
all.equal(pweibull(x, shape = 1, scale = pi), pexp(x, rate = 1/pi))
## Cumulative hazard H():
all.equal(pweibull(x, 2.5, pi, lower.tail = FALSE, log.p = TRUE),
          -(x/pi)^2.5, tolerance = 1e-15)
all.equal(qweibull(x/11, shape = 1, scale = pi), qexp(x/11, rate = 1/pi))
```

---

weighted.mean

*Weighted Arithmetic Mean*

---

## Description

Compute a weighted mean.

## Usage

```
weighted.mean(x, w, ...)

## Default S3 method:
weighted.mean(x, w, ..., na.rm = FALSE)
```

## Arguments

|                    |                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | an object containing the values whose weighted mean is to be computed.                                                     |
| <code>w</code>     | a numerical vector of weights the same length as <code>x</code> giving the weights to use for elements of <code>x</code> . |
| <code>...</code>   | arguments to be passed to or from methods.                                                                                 |
| <code>na.rm</code> | a logical value indicating whether NA values in <code>x</code> should be stripped before the computation proceeds.         |

## Details

This is a generic function and methods can be defined for the first argument `x`: apart from the default methods there are methods for the date-time classes "POSIXct", "POSIXlt", "difftime" and "Date". The default method will work for any numeric-like object for which `[]`, multiplication, division and [sum](#) have suitable methods, including complex vectors.

If `w` is missing then all elements of `x` are given the same weight, otherwise the weights coerced to numeric by [as.numeric](#) and normalized to sum to one (if possible: if their sum is zero or infinite the value is likely to be NaN).

Missing values in `w` are not handled specially and so give a missing value as the result. However, zero weights *are* handled specially and the corresponding `x` values are omitted from the sum.

## Value

For the default method, a length-one numeric vector.

**See Also**[mean](#)**Examples**

```
## GPA from Siegel 1994
wt <- c(5, 5, 4, 1)/15
x <- c(3.7, 3.3, 3.5, 2.8)
xm <- weighted.mean(x, wt)
```

---

|                    |                                   |
|--------------------|-----------------------------------|
| weighted.residuals | <i>Compute Weighted Residuals</i> |
|--------------------|-----------------------------------|

---

**Description**

Computed weighted residuals from a linear model fit.

**Usage**

```
weighted.residuals(obj, drop0 = TRUE)
```

**Arguments**

|       |                                                                          |
|-------|--------------------------------------------------------------------------|
| obj   | R object, typically of class <a href="#">lm</a> or <a href="#">glm</a> . |
| drop0 | logical. If TRUE, drop all cases with <a href="#">weights</a> == 0.      |

**Details**

Weighted residuals are based on the deviance residuals, which for a [lm](#) fit are the raw residuals  $R_i$  multiplied by  $\sqrt{w_i}$ , where  $w_i$  are the weights as specified in [lm](#)'s call.

Dropping cases with weights zero is compatible with [influence](#) and related functions.

**Value**

Numeric vector of length  $n'$ , where  $n'$  is the number of non-0 weights (`drop0 = TRUE`) or the number of observations, otherwise.

**See Also**

[residuals](#), [lm.influence](#), etc.

**Examples**

```
## following on from example(lm)

all.equal(weighted.residuals(lm.D9),
          residuals(lm.D9))
x <- 1:10
w <- 0:9
y <- rnorm(x)
weighted.residuals(lmxy <- lm(y ~ x, weights = w))
weighted.residuals(lmxy, drop0 = FALSE)
```

weights

*Extract Model Weights***Description**

weights is a generic function which extracts fitting weights from objects returned by modeling functions.

Methods can make use of [napredict](#) methods to compensate for the omission of missing values. The default methods does so.

**Usage**

```
weights(object, ...)
```

**Arguments**

object            an object for which the extraction of model weights is meaningful.  
 ...              other arguments passed to methods.

**Value**

Weights extracted from the object object: the default method looks for component "weights" and if not NULL calls [napredict](#) on it.

**References**

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

**See Also**

---

|             |                                                |
|-------------|------------------------------------------------|
| wilcox.test | <i>Wilcoxon Rank Sum and Signed Rank Tests</i> |
|-------------|------------------------------------------------|

---

**Description**

Performs one- and two-sample Wilcoxon tests on vectors of data; the latter is also known as ‘Mann-Whitney’ test.

**Usage**

```
wilcox.test(x, ...)

## Default S3 method:
wilcox.test(x, y = NULL,
            alternative = c("two.sided", "less", "greater"),
            mu = 0, paired = FALSE, exact = NULL, correct = TRUE,
            conf.int = FALSE, conf.level = 0.95, ...)

## S3 method for class 'formula'
wilcox.test(formula, data, subset, na.action, ...)
```

**Arguments**

|             |                                                                                                                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | numeric vector of data values. Non-finite (e.g., infinite or missing) values will be omitted.                                                                                                  |
| y           | an optional numeric vector of data values: as with x non-finite values will be omitted.                                                                                                        |
| alternative | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.                                  |
| mu          | a number specifying an optional parameter used to form the null hypothesis. See ‘Details’.                                                                                                     |
| paired      | a logical indicating whether you want a paired test.                                                                                                                                           |
| exact       | a logical indicating whether an exact p-value should be computed.                                                                                                                              |
| correct     | a logical indicating whether to apply continuity correction in the normal approximation for the p-value.                                                                                       |
| conf.int    | a logical indicating whether a confidence interval should be computed.                                                                                                                         |
| conf.level  | confidence level of the interval.                                                                                                                                                              |
| formula     | a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.                                       |
| data        | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula formula. By default the variables are taken from environment(formula). |
| subset      | an optional vector specifying a subset of observations to be used.                                                                                                                             |

`na.action` a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.

... further arguments to be passed to or from methods.

## Details

The formula interface is only applicable for the 2-sample tests.

If only  $x$  is given, or if both  $x$  and  $y$  are given and `paired` is `TRUE`, a Wilcoxon signed rank test of the null that the distribution of  $x$  (in the one sample case) or of  $x - y$  (in the paired two sample case) is symmetric about  $\mu$  is performed.

Otherwise, if both  $x$  and  $y$  are given and `paired` is `FALSE`, a Wilcoxon rank sum test (equivalent to the Mann-Whitney test: see the Note) is carried out. In this case, the null hypothesis is that the distributions of  $x$  and  $y$  differ by a location shift of  $\mu$  and the alternative is that they differ by some other location shift (and the one-sided alternative "greater" is that  $x$  is shifted to the right of  $y$ ).

By default (if `exact` is not specified), an exact p-value is computed if the samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

Optionally (if argument `conf.int` is true), a nonparametric confidence interval and an estimator for the pseudomedian (one-sample case) or for the difference of the location parameters  $x - y$  is computed. (The pseudomedian of a distribution  $F$  is the median of the distribution of  $(u + v)/2$ , where  $u$  and  $v$  are independent, each with distribution  $F$ . If  $F$  is symmetric, then the pseudomedian and median coincide. See Hollander & Wolfe (1973), page 34.) Note that in the two-sample case the estimator for the difference in location parameters does **not** estimate the difference in medians (a common misconception) but rather the median of the difference between a sample from  $x$  and a sample from  $y$ .

If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations. These are continuity-corrected for the interval but *not* the estimate (as the correction depends on the alternative).

With small samples it may not be possible to achieve very high confidence interval coverages. If this happens a warning will be given and an interval with lower coverage will be substituted.

## Value

A list with class "htest" containing the following components:

|                          |                                                                                                                          |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>statistic</code>   | the value of the test statistic with a name describing it.                                                               |
| <code>parameter</code>   | the parameter(s) for the exact distribution of the test statistic.                                                       |
| <code>p.value</code>     | the p-value for the test.                                                                                                |
| <code>null.value</code>  | the location parameter $\mu$ .                                                                                           |
| <code>alternative</code> | a character string describing the alternative hypothesis.                                                                |
| <code>method</code>      | the type of test applied.                                                                                                |
| <code>data.name</code>   | a character string giving the names of the data.                                                                         |
| <code>conf.int</code>    | a confidence interval for the location parameter. (Only present if argument <code>conf.int</code> = <code>TRUE</code> .) |
| <code>estimate</code>    | an estimate of the location parameter. (Only present if argument <code>conf.int</code> = <code>TRUE</code> .)            |

**Warning**

This function can use large amounts of memory and stack (and even crash R if the stack limit is exceeded) if `exact = TRUE` and one sample is large (several thousands or more).

**Note**

The literature is not unanimous about the definitions of the Wilcoxon rank sum and Mann-Whitney tests. The two most common definitions correspond to the sum of the ranks of the first sample with the minimum value subtracted or not: R subtracts and S-PLUS does not, giving a value which is larger by  $m(m+1)/2$  for a first sample of size  $m$ . (It seems Wilcoxon's original paper used the unadjusted sum of the ranks but subsequent tables subtracted the minimum.)

R's value can also be computed as the number of all pairs  $(x[i], y[j])$  for which  $y[j]$  is not greater than  $x[i]$ , the most common definition of the Mann-Whitney test.

Wilcoxon

---

*Distribution of the Wilcoxon Rank Sum Statistic*

---

## Description

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon rank sum statistic obtained from samples with size  $m$  and  $n$ , respectively.

## Usage

```
dwilcox(x, m, n, log = FALSE)
pwilcox(q, m, n, lower.tail = TRUE, log.p = FALSE)
qwilcox(p, m, n, lower.tail = TRUE, log.p = FALSE)
rwilcox(nn, m, n)
```

## Arguments

|                         |                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles.                                                                                       |
| <code>p</code>          | vector of probabilities.                                                                                   |
| <code>nn</code>         | number of observations. If <code>length(nn) &gt; 1</code> , the length is taken to be the number required. |
| <code>m, n</code>       | numbers of observations in the first and second sample, respectively. Can be vectors of positive integers. |
| <code>log, log.p</code> | logical; if TRUE, probabilities $p$ are given as $\log(p)$ .                                               |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                      |

## Details

This distribution is obtained as follows. Let  $x$  and  $y$  be two random, independent samples of size  $m$  and  $n$ . Then the Wilcoxon rank sum statistic is the number of all pairs  $(x[i], y[j])$  for which  $y[j]$  is not greater than  $x[i]$ . This statistic takes values between 0 and  $m * n$ , and its mean and variance are  $m * n / 2$  and  $m * n * (m + n + 1) / 12$ , respectively.

If any of the first three arguments are vectors, the recycling rule is used to do the calculations for all combinations of the three up to the length of the longest vector.

## Value

`dwilcox` gives the density, `pwilcox` gives the distribution function, `qwilcox` gives the quantile function, and `rwilcox` generates random deviates.

The length of the result is determined by `nn` for `rwilcox`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `nn` are recycled to the length of the result. Only the first elements of the logical arguments are used.

## Warning

These functions can use large amounts of memory and stack (and even crash **R** if the stack limit is exceeded and stack-checking is not in place) if one sample is large (several thousands or more).

## Note

S-PLUS uses a different (but equivalent) definition of the Wilcoxon statistic: see [wilcox.test](#) for details.

## Author(s)

Kurt Hornik

## Source

These are calculated via recursion, based on `cwilcox(k, m, n)`, the number of choices with statistic  $k$  from samples of size  $m$  and  $n$ , which is itself calculated recursively and the results cached. Then `dwilcox` and `pwilcox` sum appropriate values of `cwilcox`, and `qwilcox` is based on inversion.

`rwilcox` generates a random permutation of ranks and evaluates the statistic.

## See Also

[wilcox.test](#) to calculate the statistic from data, find p values and so on.

       main = paste("Q-Q-Plot of empirical and theoretical quantiles",
                    "Wilcoxon Statistic, (m=4, n=6)", sep = "\n"))
n <- as.numeric(names(print(tU <- table(U))))
text(n+.2, n+.5, labels = tU, col = "red")
```

---

window

*Time Windows*

---

## Description

window is a generic function which extracts the subset of the object x observed between the times start and end. If a frequency is specified, the series is then re-sampled at the new frequency.

## Usage

```
window(x, ...)
## S3 method for class 'ts'
window(x, ...)
## Default S3 method:
window(x, start = NULL, end = NULL,
       frequency = NULL, deltat = NULL, extend = FALSE, ...)

window(x, ...) <- value
## S3 replacement method for class 'ts'
window(x, start, end, frequency, deltat, ...) <- value
```

**Arguments**

|                                |                                                                                                                                                                                |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                 | a time-series (or other object if not replacing values).                                                                                                                       |
| <code>start</code>             | the start time of the period of interest.                                                                                                                                      |
| <code>end</code>               | the end time of the period of interest.                                                                                                                                        |
| <code>frequency, deltat</code> | the new frequency can be specified by either (or both if they are consistent).                                                                                                 |
| <code>extend</code>            | logical. If true, the <code>start</code> and <code>end</code> values are allowed to extend the series. If false, attempts to extend the series give a warning and are ignored. |
| <code>...</code>               | further arguments passed to or from other methods.                                                                                                                             |
| <code>value</code>             | replacement values.                                                                                                                                                            |

**Details**

The start and end times can be specified as for [ts](#). If there is no observation at the new `start` or `end`, the immediately following (`start`) or preceding (`end`) observation time is used.

The replacement function has a method for `ts` objects, and is allowed to extend the series (with a warning). There is no default method.

**Value**

The value depends on the method. `window.default` will return a vector or matrix with an appropriate [tsp](#) attribute.

`window.ts` differs from `window.default` only in ensuring the result is a `ts` object.

If `extend = TRUE` the series will be padded with NAs if needed.

xtabs

*Cross Tabulation***Description**

Create a contingency table (optionally a sparse matrix) from cross-classifying factors, usually contained in a data frame, using a formula interface.

**Usage**

```
xtabs(formula = ~., data = parent.frame(), subset, sparse = FALSE,
      na.action, exclude = c(NA, NaN), drop.unused.levels = FALSE)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula            | a <a href="#">formula</a> object with the cross-classifying variables (separated by +) on the right hand side (or an object which can be coerced to a formula). Interactions are not allowed. On the left hand side, one may optionally give a vector or a matrix of counts; in the latter case, the columns are interpreted as corresponding to the levels of a variable. This is useful if the data have already been tabulated, see the examples below. |
| data               | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula formula. By default the variables are taken from <code>environment(formula)</code> .                                                                                                                                                                                                                                               |
| subset             | an optional vector specifying a subset of observations to be used.                                                                                                                                                                                                                                                                                                                                                                                         |
| sparse             | logical specifying if the result should be a <i>sparse</i> matrix, i.e., inheriting from <a href="#">sparseMatrix</a> Only works for two factors (since there are no higher-order sparse array classes yet).                                                                                                                                                                                                                                               |
| na.action          | a function which indicates what should happen when the data contain NAs.                                                                                                                                                                                                                                                                                                                                                                                   |
| exclude            | a vector of values to be excluded when forming the set of levels of the classifying factors.                                                                                                                                                                                                                                                                                                                                                               |
| drop.unused.levels | a logical indicating whether to drop unused levels in the classifying factors. If this is FALSE and there are unused levels, the table will contain zero marginals, and a subsequent chi-squared test for independence of the factors will not work.                                                                                                                                                                                                       |

**Details**

There is a `summary` method for contingency table objects created by `table` or `xtabs(*, sparse = FALSE)`, which gives basic information and performs a chi-squared test for independence of factors (note that the function [chisq.test](#) currently only handles 2-d tables).

If a left hand side is given in `formula`, its entries are simply summed over the cells corresponding to the right hand side; this also works if the lhs does not give counts.

For variables in `formula` which are factors, `exclude` must be specified explicitly; the default exclusions will not be used.

**Value**

By default, when `sparse = FALSE`, a contingency table in array representation of S3 class `c("xtabs", "table")`, with a "call" attribute storing the matched call.

When `sparse = TRUE`, a sparse numeric matrix, specifically an object of S4 class `dgTMatrix` from package **Matrix**.

**See Also**

`table` for traditional cross-tabulation, and `as.data.frame.table` which is the inverse operation of `xtabs` (see the DF example below).

`sparseMatrix` on sparse matrices in package **Matrix**.

**Examples**

```
## 'esoph' has the frequencies of cases and controls for all levels of
## the variables 'agegp', 'alcgp', and 'tobgp'.
xtabs(cbind(ncases, ncontrols) ~ ., data = esoph)
## Output is not really helpful ... flat tables are better:
ftable(xtabs(cbind(ncases, ncontrols) ~ ., data = esoph))
## In particular if we have fewer factors ...
ftable(xtabs(cbind(ncases, ncontrols) ~ agegp, data = esoph))

## This is already a contingency table in array form.
DF <- as.data.frame(UCBAdmissions)
## Now 'DF' is a data frame with a grid of the factors and the counts
## in variable 'Freq'.
DF
## Nice for taking margins ...
xtabs(Freq ~ Gender + Admit, DF)
## And for testing independence ...
summary(xtabs(Freq ~ ., DF))

## Create a nice display for the warp break data.
warpbreaks$replicate <- rep(1:9, len = 54)
ftable(xtabs(breaks ~ wool + tension + replicate, data = warpbreaks))

### ---- Sparse Examples ----

if(require("Matrix")) {
  ## similar to "nlme"s 'ergoStool' :
  d.ergo <- data.frame(Type = paste0("T", rep(1:4, 9*4)),
                      Subj = gl(9, 4, 36*4))
  print(xtabs(~ Type + Subj, data = d.ergo)) # 4 replicates each
  set.seed(15) # a subset of cases:
  print(xtabs(~ Type + Subj, data = d.ergo[sample(36, 10), ], sparse = TRUE))

  ## Hypothetical two-level setup:
  inner <- factor(sample(letters[1:25], 100, replace = TRUE))
  inout <- factor(sample(LETTERS[1:5], 25, replace = TRUE))
  fr <- data.frame(inner = inner, outer = inout[as.integer(inner)])
  print(xtabs(~ inner + outer, fr, sparse = TRUE))
}
```

```
}
```

## Chapter 11

# The stats4 package

---

stats4-package

*Statistical Functions using S4 Classes*

---

### Description

Statistical Functions using S4 classes.

### Details

This package contains functions and classes for statistics using the [S version 4](#) class system.

The methods currently support maximum likelihood (function [mle\(\)](#) returning class "[mle](#)"), including methods for [logLik](#) for use with [AIC](#).

### Author(s)

R Core Team and contributors worldwide

Maintainer: R Core Team <[R-core@r-project.org](mailto:R-core@r-project.org)>

---

coef-methods

*Methods for Function coef in Package stats4*

---

### Description

Extract the coefficient vector from "[mle](#)" objects.

### Methods

`signature(object = "ANY")` Generic function: see [coef](#).

`signature(object = "mle")` Extract the full coefficient vector (including any fixed coefficients) from the fit.

`signature(object = "summary.mle")` Extract the coefficient vector and standard errors from the summary of the fit.

---

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| confint-methods | <i>Methods for Function confint in Package stats4</i> |
|-----------------|-------------------------------------------------------|

---

### Description

Generate confidence intervals

### Methods

signature(object = "ANY") Generic function: see [confint](#).

signature(object = "mle") First generate profile and then confidence intervals from the profile.

signature(object = "profile.mle") Generate confidence intervals based on likelihood profile.

---

|                |                                                      |
|----------------|------------------------------------------------------|
| logLik-methods | <i>Methods for Function logLik in Package stats4</i> |
|----------------|------------------------------------------------------|

---

### Description

Extract the maximized log-likelihood from "mle" objects.

### Methods

signature(object = "ANY") Generic function: see [logLik](#).

signature(object = "mle") Extract log-likelihood from the fit.

### Note

The mle method does not know about the number of observations unless nobs was specified on the call and so may not be suitable for use with [BIC](#).

---

|     |                                      |
|-----|--------------------------------------|
| mle | <i>Maximum Likelihood Estimation</i> |
|-----|--------------------------------------|

---

**Description**

Estimate parameters by the method of maximum likelihood.

**Usage**

```
mle(minuslogl, start = formals(minuslogl), method = "BFGS",  
    fixed = list(), nobs, ...)
```

**Arguments**

|           |                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------|
| minuslogl | Function to calculate negative log-likelihood.                                                    |
| start     | Named list. Initial values for optimizer.                                                         |
| method    | Optimization method to use. See <a href="#">optim</a> .                                           |
| fixed     | Named list. Parameter values to keep fixed during optimization.                                   |
| nobs      | optional integer: the number of observations, to be used for e.g. computing <a href="#">BIC</a> . |
| ...       | Further arguments to pass to <a href="#">optim</a> .                                              |

**Details**

The [optim](#) optimizer is used to find the minimum of the negative log-likelihood. An approximate covariance matrix for the parameters is obtained by inverting the Hessian matrix at the optimum.

**Value**

An object of class [mle-class](#).

**Note**

Be careful to note that the argument is  $-\log L$  (not  $-2 \log L$ ). It is for the user to ensure that the likelihood is correct, and that asymptotic likelihood inference is valid.

**See Also**

[mle-class](#)

**Examples**

```
## Avoid printing to unwarranted accuracy  
od <- options(digits = 5)  
x <- 0:10  
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)  
  
## Easy one-dimensional MLE:
```

```

nLL <- function(lambda) -sum(stats::dpois(y, lambda, log = TRUE))
fit0 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y))
# For 1D, this is preferable:
fit1 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y),
           method = "Brent", lower = 1, upper = 20)
stopifnot(nobs(fit0) == length(y))

## This needs a constrained parameter space: most methods will accept NA
ll <- function(ymax = 15, xhalf = 6) {
  if(ymax > 0 && xhalf > 0)
    -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
  else NA
}
(fit <- mle(ll, nobs = length(y)))
mle(ll, fixed = list(xhalf = 6))
## alternative using bounds on optimization
ll2 <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
mle(ll2, method = "L-BFGS-B", lower = rep(0, 2))

AIC(fit)
BIC(fit)

summary(fit)
logLik(fit)
vcov(fit)
plot(profile(fit), absVal = FALSE)
confint(fit)

## Use bounded optimization
## The lower bounds are really > 0,
## but we use >=0 to stress-test profiling
(fit2 <- mle(ll, method = "L-BFGS-B", lower = c(0, 0)))
plot(profile(fit2), absVal = FALSE)

## a better parametrization:
ll3 <- function(lymax = log(15), lxhalf = log(6))
  -sum(stats::dpois(y, lambda = exp(lymax)/(1+x/exp(lxhalf)), log = TRUE))
(fit3 <- mle(ll3))
plot(profile(fit3), absVal = FALSE)
exp(confint(fit3))

options(od)

```

---

mle-class

---

Class "mle" for Results of Maximum Likelihood Estimation

---

## Description

This class encapsulates results of a generic maximum likelihood procedure.

## Objects from the Class

Objects can be created by calls of the form `new("mle", ...)`, but most often as the result of a call to `mle`.

## Slots

**call**: Object of class "language". The call to `mle`.  
**coef**: Object of class "numeric". Estimated parameters.  
**fullcoef**: Object of class "numeric". Fixed and estimated parameters.  
**vcov**: Object of class "matrix". Approximate variance-covariance matrix.  
**min**: Object of class "numeric". Minimum value of objective function.  
**details**: a "list", as returned from `optim`.  
**minuslogl**: Object of class "function". The negative loglikelihood function.  
**nobs**: "integer" of length one. The number of observations (often NA, when not set in call explicitly).  
**method**: Object of class "character". The optimization method used.

## Methods

**confint** signature(object = "mle"): Confidence intervals from likelihood profiles.  
**logLik** signature(object = "mle"): Extract maximized log-likelihood.  
**profile** signature(fitted = "mle"): Likelihood profile generation.  
**nobs** signature(object = "mle"): Number of observations, here simply accessing the nobs slot mentioned above.  
**show** signature(object = "mle"): Display object briefly.  
**summary** signature(object = "mle"): Generate object summary.  
**update** signature(object = "mle"): Update fit.  
**vcov** signature(object = "mle"): Extract variance-covariance matrix.

---

plot-methods

*Methods for Function plot in Package stats4*

---

## Description

Plot profile likelihoods for "mle" objects.

## Usage

```
## S4 method for signature 'profile.mle,missing'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100, nseg = 50,
     absVal = TRUE, ...)
```

Arguments

|        |                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | an object of class "profile.mle"                                                                                                                          |
| levels | levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually conf is used instead of giving levels explicitly. |
| conf   | a numeric vector of confidence levels for profile-based confidence intervals on the parameters.                                                           |
| nseg   | an integer value giving the number of segments to use in the spline interpolation of the profile t curves.                                                |
| absVal | a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to TRUE.                      |
| ...    | other arguments to the plot function can be passed here.                                                                                                  |

Methods

|                                             |                                              |
|---------------------------------------------|----------------------------------------------|
| signature(x = "ANY", y = "ANY")             | Generic function: see <a href="#">plot</a> . |
| signature(x = "profile.mle", y = "missing") | Plot likelihood profiles for x.              |

---

|                 |                                                              |
|-----------------|--------------------------------------------------------------|
| profile-methods | <i>Methods for Function profile in Package <b>stats4</b></i> |
|-----------------|--------------------------------------------------------------|

---

Description

Profile likelihood for "mle" objects.

Usage

```
## S4 method for signature 'mle'
profile(fitted, which = 1:p, maxsteps = 100, alpha = 0.01,
        zmax = sqrt(qchisq(1 - alpha, 1L)), del = zmax/5,
        trace = FALSE, ...)
```

Arguments

|          |                                                                                                                             |
|----------|-----------------------------------------------------------------------------------------------------------------------------|
| fitted   | Object to be profiled                                                                                                       |
| which    | Optionally select subset of parameters to profile.                                                                          |
| maxsteps | Maximum number of steps to bracket zmax.                                                                                    |
| alpha    | Significance level corresponding to zmax, based on a Scheffe-style multiple testing interval. Ignored if zmax is specified. |
| zmax     | Cutoff for the profiled value of the signed root-likelihood.                                                                |
| del      | Initial stepsize on root-likelihood scale.                                                                                  |
| trace    | Logical. Print intermediate results.                                                                                        |
| ...      | Currently unused.                                                                                                           |

**Details**

The profiling algorithm tries to find an approximately evenly spaced set of at least five parameter values (in each direction from the optimum) to cover the root-likelihood function. Some care is taken to try and get sensible results in cases of high parameter curvature. Notice that it may not always be possible to obtain the cutoff value, since the likelihood might level off.

**Value**

An object of class "profile.mle", see "profile.mle-class".

**Methods**

`signature(fitted = "ANY")` Generic function: see [profile](#).

`signature(fitted = "mle")` Profile the likelihood in the vicinity of the optimum of an "mle" object.

---

|                   |                                                                    |
|-------------------|--------------------------------------------------------------------|
| profile.mle-class | <i>Class "profile.mle"; Profiling information for "mle" object</i> |
|-------------------|--------------------------------------------------------------------|

---

**Description**

Likelihood profiles along each parameter of likelihood function

**Objects from the Class**

Objects can be created by calls of the form `new("profile.mle", ...)`, but most often by invoking `profile` on an "mle" object.

**Slots**

**profile:** Object of class "list". List of profiles, one for each requested parameter. Each profile is a data frame with the first column called `z` being the signed square root of the -2 log likelihood ratio, and the others being the parameters with names prefixed by `par.vals`.

**summary:** Object of class "summary.mle". Summary of object being profiled.

**Methods**

**confint** `signature(object = "profile.mle")`: Use profile to generate approximate confidence intervals for parameters.

**plot** `signature(x = "profile.mle", y = "missing")`: Plot profiles for each parameter.

**See Also**

[mle](#), [mle-class](#), [summary.mle-class](#)

---

|              |                                                           |
|--------------|-----------------------------------------------------------|
| show-methods | <i>Methods for Function</i> show in Package <b>stats4</b> |
|--------------|-----------------------------------------------------------|

---

**Description**

Show objects of classes mle and summary.mle

**Methods**

signature(object = "mle") Print simple summary of mle object. Just the coefficients and the call.

signature(object = "summary.mle") Shows call, table of coefficients and standard errors, and  $-2 \log L$ .

---

|                 |                                                              |
|-----------------|--------------------------------------------------------------|
| summary-methods | <i>Methods for Function</i> summary in Package <b>stats4</b> |
|-----------------|--------------------------------------------------------------|

---

**Description**

Summarize objects

**Methods**

signature(object = "ANY") Generic function

signature(object = "mle") Generate a summary as an object of class "summary.mle", containing estimates, asymptotic SE, and value of  $-2 \log L$ .

---

|                   |                                                      |
|-------------------|------------------------------------------------------|
| summary.mle-class | <i>Class "summary.mle", Summary of "mle" Objects</i> |
|-------------------|------------------------------------------------------|

---

**Description**

Extract of "mle" object

**Objects from the Class**

Objects can be created by calls of the form new("summary.mle", ...), but most often by invoking summary on an "mle" object. They contain values meant for printing by show.

**Slots**

call: Object of class "language" The call that generated the "mle" object.

coef: Object of class "matrix". Estimated coefficients and standard errors

m2logL: Object of class "numeric". Minus twice the log likelihood.

**Methods**

**show** signature(object = "summary.mle"): Pretty-prints object

**coef** signature(object = "summary.mle"): Extracts the contents of the coef slot

**See Also**

|                |                                                      |
|----------------|------------------------------------------------------|
| update-methods | <i>Methods for Function update in Package stats4</i> |
|----------------|------------------------------------------------------|

---

**Description**

Update "mle" objects.

**Usage**

```
## S4 method for signature 'mle'
update(object, ..., evaluate = TRUE)
```

**Arguments**

|          |                                                                                                                  |
|----------|------------------------------------------------------------------------------------------------------------------|
| object   | An existing fit.                                                                                                 |
| ...      | Additional arguments to the call, or arguments with changed values. Use name = NULL to remove the argument name. |
| evaluate | If true evaluate the new call else return the call.                                                              |

**Methods**

signature(object = "ANY") Generic function: see [update](#).

signature(object = "mle") Update a fit.

**Examples**

```
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
ll <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
fit <- mle(ll)
## note the recorded call contains ..1, a problem with S4 dispatch
update(fit, fixed = list(xhalf = 3))
```

---

vcov-methods*Methods for Function vcov in Package stats4*

---

**Description**

Extract the approximate variance-covariance matrix from "mle" objects.

**Methods**

signature(object = "ANY") Generic function: see [vcov](#).

signature(object = "mle") Extract the estimated variance-covariance matrix for the estimated parameters (if any).

## Chapter 12

# The tcltk package

---

tcltk-package

*Tcl/Tk Interface*

---

### Description

Interface and language bindings to Tcl/Tk GUI elements.

### Details

This package provides access to the platform-independent Tcl scripting language and Tk GUI elements. See [TkWidgets](#) for a list of supported widgets, [TkWidgetcmds](#) for commands to work with them, and references in those files for more.

The Tcl/Tk documentation is in the system man pages.

For a complete list of functions, use `ls("package:tcltk")`.

Note that Tk will not be initialized if there is no `DISPLAY` variable set, but Tcl can still be used. This is most useful to allow the loading of a package which depends on **tcltk** in a session that does not actually use it (e.g., during installation).

TclInterface

*Low-level Tcl/Tk Interface***Description**

These functions and variables provide the basic glue between R and the Tcl interpreter and Tk GUI toolkit. Tk windows may be represented via R objects. Tcl variables can be accessed via objects of class `tclVar` and the C level interface to Tcl objects is accessed via objects of class `tclObj`.

**Usage**

```
.Tcl(...)
.Tcl.objv(objv)
.Tcl.args(...)
.Tcl.args.objv(...)
.Tcl.callback(...)
.Tk.ID(win)
.Tk.newwin(ID)
.Tk.subwin(parent)
.TkRoot

tkdestroy(win)
is.tkwin(x)

tclvalue(x)
tclvalue(x) <- value

tclVar(init = "")
## S3 method for class 'tclVar'
as.character(x, ...)
## S3 method for class 'tclVar'
tclvalue(x)
## S3 replacement method for class 'tclVar'
tclvalue(x) <- value

tclArray()
## S3 method for class 'tclArray'
x[[...]]
## S3 replacement method for class 'tclArray'
x[[...]] <- value
## S3 method for class 'tclArray'
x$i
## S3 replacement method for class 'tclArray'
x$i <- value

## S3 method for class 'tclArray'
names(x)
```

```

## S3 method for class 'tclArray'
length(x)

tclObj(x)
tclObj(x) <- value
## S3 method for class 'tclVar'
tclObj(x)
## S3 replacement method for class 'tclVar'
tclObj(x) <- value

as.tclObj(x, drop = FALSE)
is.tclObj(x)

## S3 method for class 'tclObj'
as.character(x, ...)
## S3 method for class 'tclObj'
as.integer(x, ...)
## S3 method for class 'tclObj'
as.double(x, ...)
## S3 method for class 'tclObj'
as.logical(x, ...)
## S3 method for class 'tclObj'
as.raw(x, ...)
## S3 method for class 'tclObj'
tclvalue(x)

## Default S3 method:
tclvalue(x)
## Default S3 replacement method:
tclvalue(x) <- value

addTclPath(path = ".")
tclRequire(package, warn = TRUE)
tclVersion()

```

### Arguments

|                    |                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>objv</code>  | a named vector of Tcl objects                                                                                                          |
| <code>win</code>   | a window structure                                                                                                                     |
| <code>x</code>     | an object                                                                                                                              |
| <code>i</code>     | character or (unquoted) name                                                                                                           |
| <code>drop</code>  | logical. Indicates whether a single-element vector should be made into a simple Tcl object or a list of length one                     |
| <code>value</code> | For <code>tclvalue</code> assignments, a character string. For <code>tclObj</code> assignments, an object of class <code>tclObj</code> |
| <code>ID</code>    | a window ID                                                                                                                            |

|         |                                                           |
|---------|-----------------------------------------------------------|
| parent  | a window which becomes the parent of the resulting window |
| path    | path to a directory containing Tcl packages               |
| package | a Tcl package name                                        |
| warn    | logical. Warn if not found?                               |
| ...     | Additional arguments. See below.                          |
| init    | initialization value                                      |

## Details

Many of these functions are not intended for general use but are used internally by the commands that create and manipulate Tk widgets and Tcl objects. At the lowest level `.Tcl` sends a command as a text string to the Tcl interpreter and returns the result as an object of class `tclObj` (see below). A newer variant `.Tcl.objv` accepts arguments in the form of a named list of `tclObj` objects.

`.Tcl.args` converts an R argument list of `tag = value` pairs to the Tcl `-option value` style, thus enabling a simple translation between the two languages. To send a value with no preceding option flag to Tcl, just use an untagged argument. In the rare case one needs an option with no subsequent value `tag = NULL` can be used. Most values are just converted to character mode and inserted in the command string, but window objects are passed using their ID string, and callbacks are passed via the result of `.Tcl.callback`. Tags are converted to option flags simply by prepending a `-`.

`.Tcl.args.objv` serves a similar purpose as `.Tcl.args` but produces a list of `tclObj` objects suitable for passing to `.Tcl.objv`. The names of the list are converted to Tcl option style internally by `.Tcl.objv`.

Callbacks can be either *atomic callbacks* handled by `.Tcl.callback` or expressions. An expression is treated as a list of atomic callbacks, with the following exceptions: if an element is a name, it is first evaluated in the callers frame, and likewise if it is an explicit function definition; the break expression is translated directly to the Tcl counterpart. `.Tcl.callback` converts R functions and unevaluated calls to Tcl command strings. The argument must be either a function closure or an object of mode "call" followed by an environment. The return value in the first case is of the form `R_call 0x408b94d4` in which the hexadecimal number is the memory address of the function. In the second case it will be of the form `R_call_lang 0x8a95904 0x819bfd0`. For expressions, a sequence of similar items is generated, separated by semicolons. `.Tcl.args` takes special precautions to ensure that functions or calls will continue to exist at the specified address by assigning the callback into the relevant window environment (see below).

Tk windows are represented as objects of class `tkwin` which are lists containing a ID field and an `env` field which is an R environments, enclosed in the global environment. The value of the ID field is identical to the Tk window name. The `env` environment contains a `parent` variable and a `num.subwin` variable. If the window obtains sub-windows and callbacks, they are added as variables to the environment. `.TkRoot` is the top window with ID `"."`; this window is not displayed in order to avoid ill effects of closing it via window manager controls. The `parent` variable is undefined for `.TkRoot`.

`.Tk.ID` extracts the ID of a window, `.Tk.newwin` creates a new window environment with a given ID and `.Tk.subwin` creates a new window which is a sub-window of a given parent window.

`tkdestroy` destroys a window and also removes the reference to a window from its parent.

`is.tkwin` can be used to test whether a given object is a window environment.

`tclVar` creates a new Tcl variable and initializes it to `init`. An R object of class `tclVar` is created to represent it. Using `as.character` on the object returns the Tcl variable name. Accessing the Tcl variable from R is done using the `tclvalue` function, which can also occur on the left-hand side of assignments. If `tclvalue` is passed an argument which is not a `tclVar` object, then it will assume that it is a character string explicitly naming global Tcl variable. Tcl variables created by `tclVar` are uniquely named and automatically unset by the garbage collector when the representing object is no longer in use.

`tclArray` creates a new Tcl array and initializes it to the empty array. An R object of class `tclArray` and inheriting from class `tclVar` is created to represent it. You can access elements of the Tcl array using indexing with `[]` or `$`, which also allow replacement forms. Notice that Tcl arrays are associative by nature and hence unordered; indexing with a numeric index `i` refers to the element with the *name* `as.character(i)`. Multiple indices are pasted together separated by commas to form a single name. You can query the length and the set of names in an array using methods for `length` and `names`, respectively; these cannot meaningfully be set so assignment forms exist only to print an error message.

It is possible to access Tcl's 'dual-ported' objects directly, thus avoiding parsing and deparsing of their string representation. This works by using objects of class `tclObj`. The string representation of such objects can be extracted (but not set) using `tclvalue` and conversion to vectors of mode `"character"`, `"double"`, `"integer"`, `"logical"`, and `"raw"` is performed using the standard coercion functions `as.character`, etc. Conversely, such vectors can be converted using `as.tclObj`. There is an ambiguity as to what should happen for length one vectors, controlled by the `drop` argument; there are cases where the distinction matters to Tcl, although mostly it treats them equivalently. Notice that `tclvalue` and `as.character` differ on an object whose string representation has embedded spaces, the former is sometimes to be preferred, in particular when applied to the result of `tclread`, `tkgetOpenFile`, and similar functions. The `as.raw` method returns a raw vector or a list of raw vectors and can be used to return binary data from Tcl.

The object behind a `tclVar` object is extracted using `tclObj(x)` which also allows an assignment form, in which the right hand side of the assignment is automatically converted using `as.tclObj`. There is a print method for `tclObj` objects; it prints `<Tcl>` followed by the string representation of the object. Notice that `as.character` on a `tclVar` object is the *name* of the corresponding Tcl variable and not the value.

Tcl packages can be loaded with `tclRequire`; it may be necessary to add the directory where they are found to the Tcl search path with `addTclPath`. The return value is a class `"tclObj"` object if it succeeds, or `FALSE` if it fails (when a warning is issued). To see the current search path as an R character vector, use

```
strsplit(tclvalue('auto_path'), " ")[[1]]
```

.

The Tcl version (including `patchlevel`) is returned as a character string (such as `"8.6.3"`).

### Note

Strings containing unbalanced braces are currently not handled well in many circumstances.

### See Also

[TkWidgets](#), [TkCommands](#), [TkWidgetcmds](#).

`capabilities("tcltk")` to see if Tcl/Tk support was compiled into this build of R.

### Examples

```
tclVersion()

## Not run:
## These cannot be run by example() but should be OK when pasted
## into an interactive R session with the tcltk package loaded
.Tcl("format \"%s\n\" \"Hello, World!\")
f <- function()cat("HI!\n")
.Tcl.callback(f)
.Tcl.args(text = "Push!", command = f) # NB: Different address

xyzy <- tclVar(7913)
tclvalue(xyzy)
tclvalue(xyzy) <- "foo"
as.character(xyzy)
tcl("set", as.character(xyzy))

top <- tktoplevel() # a Tk widget, see Tk-widgets
ls(envir = top$env, all = TRUE)
ls(envir = .TkRoot$env, all = TRUE) # .Tcl.args put a callback ref in here

## End(Not run)
```

---

|                |                                               |
|----------------|-----------------------------------------------|
| tclServiceMode | <i>Allow Tcl events to be serviced or not</i> |
|----------------|-----------------------------------------------|

---

### Description

This function controls or reports on the Tcl service mode, i.e., whether Tcl will respond to events.

### Usage

```
tclServiceMode(on = NULL)
```

### Arguments

`on` (logical) Whether event servicing is turned on.

### Details

If called with `on == NULL` (the default), no change is made.

Note that this blocks all Tcl/Tk activity, including for widgets from other packages. It may be better to manage mapping of windows individually.

### Value

The value of the Tcl service mode before the call.

## Examples

```
## see demo(tkcanvas) for an example
## Not run:
oldmode <- tclServiceMode(FALSE)
# Do some work to create a nice picture.
# Nothing will be displayed until...
tclServiceMode(oldmode)

## End(Not run)
## another idea is to use tkwm.withdraw() ... tkwm.deiconify()
```

---

TkCommands

*Tk non-widget commands*

---

## Description

These functions interface to Tk non-widget commands, such as the window manager interface commands and the geometry managers.

## Usage

```
tcl(...)
tktitle(x)

tktitle(x) <- value

tkbell(...)
tkbind(...)
tkbindtags(...)
tkfocus(...)
tklower(...)
tkraise(...)

tkclipboard.append(...)
tkclipboard.clear(...)

tkevent.add(...)
tkevent.delete(...)
tkevent.generate(...)
tkevent.info(...)

tkfont.actual(...)
tkfont.configure(...)
tkfont.create(...)
tkfont.delete(...)
tkfont.families(...)
tkfont.measure(...)
```

```
tkfont.metrics(...)
tkfont.names(...)

tkgrab(...)
tkgrab.current(...)
tkgrab.release(...)
tkgrab.set(...)
tkgrab.status(...)

tkimage.create(...)
tkimage.delete(...)
tkimage.height(...)
tkimage.inuse(...)
tkimage.names(...)
tkimage.type(...)
tkimage.types(...)
tkimage.width(...)

## NB: some widgets also have a selection.clear command,
## hence the "X".

tkXselection.clear(...)
tkXselection.get(...)
tkXselection.handle(...)
tkXselection.own(...)

tkwait.variable(...)
tkwait.visibility(...)
tkwait.window(...)

## wininfo actually has a large number of subcommands,
## but it's rarely used,
## so use tkwininfo("atom", ...) etc. instead.

tkwininfo(...)

# Window manager interface

tkwm.aspect(...)
tkwm.client(...)
tkwm.colormapwindows(...)
tkwm.command(...)
tkwm.deiconify(...)
tkwm.focusmodel(...)
tkwm.frame(...)
tkwm.geometry(...)
tkwm.grid(...)
tkwm.group(...)
```

```
tkwm.iconbitmap(...)
tkwm.iconify(...)
tkwm.iconmask(...)
tkwm.iconname(...)
tkwm.iconposition(...)
tkwm.iconwindow(...)
tkwm.maxsize(...)
tkwm.minsize(...)
tkwm.overrideredirect(...)
tkwm.positionfrom(...)
tkwm.protocol(...)
tkwm.resizable(...)
tkwm.sizefrom(...)
tkwm.state(...)
tkwm.title(...)
tkwm.transient(...)
tkwm.withdraw(...)
```

### ### Geometry managers

```
tkgrid(...)
tkgrid.bbox(...)
tkgrid.columnconfigure(...)
tkgrid.configure(...)
tkgrid.forget(...)
tkgrid.info(...)
tkgrid.location(...)
tkgrid.propagate(...)
tkgrid.rowconfigure(...)
tkgrid.remove(...)
tkgrid.size(...)
tkgrid.slaves(...)
```

```
tkpack(...)
tkpack.configure(...)
tkpack.forget(...)
tkpack.info(...)
tkpack.propagate(...)
tkpack.slaves(...)
```

```
tkplace(...)
tkplace.configure(...)
tkplace.forget(...)
tkplace.info(...)
tkplace.slaves(...)
```

### ## Standard dialogs

```

tkgetOpenFile(...)
tkgetSaveFile(...)
tkchooseDirectory(...)
tkmessageBox(...)
tkdialog(...)
tkpopup(...)

## File handling functions
tclfile.tail(...)
tclfile.dir(...)
tclopen(...)
tclclose(...)
tclputs(...)
tclread(...)

```

### Arguments

|       |                                              |
|-------|----------------------------------------------|
| x     | A window object                              |
| value | For tktitle assignments, a character string. |
| ...   | Handled via <code>.Tcl.args</code>           |

### Details

tcl provides a generic interface to calling any Tk or Tcl command by simply running `.Tcl.args.objv` on the argument list and passing the result to `.Tcl.objv`. Most of the other commands simply call tcl with a particular first argument and sometimes also a second argument giving the subcommand.

tktitle and its assignment form provides an alternate interface to Tk's `wm title`

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. With a few exceptions, the pattern is that Tk subcommands like `pack` `configure` are converted to function names like `tkpack.configure`, and Tcl subcommands are like `tclfile.dir`.

### See Also

[TclInterface](#), [TkWidgets](#), [TkWidgetcmds](#)

### Examples

```

## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
tkpack(l1 <- tklabel(tt, text = "Heave"), l2 <- tklabel(tt, text = "Ho"))
tkpack.configure(l1, side = "left")

## Try stretching the window and then

```

```
tkdestroy(tt)

## End(Not run)
```

---

tkpager

*Page file using Tk text widget*

---

### Description

This plugs into `file.show`, showing files in separate windows.

### Usage

```
tkpager(file, header, title, delete.file)
```

### Arguments

|                          |                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------|
| <code>file</code>        | character vector containing the names of the files to be displayed                                  |
| <code>header</code>      | headers to use for each file                                                                        |
| <code>title</code>       | common title to use for the window(s). Pasted together with the header to form actual window title. |
| <code>delete.file</code> | logical. Should file(s) be deleted after display?                                                   |

### Note

The "`\b_`" string used for underlining is currently quietly removed. The font and background colour are currently hardcoded to Courier and gray90.

### See Also

[file.show](#)

---

tkProgressBar

*Progress Bars via Tk*

---

### Description

Put up a Tk progress bar widget.

**Usage**

```
tkProgressBar(title = "R progress bar", label = "",
              min = 0, max = 1, initial = 0, width = 300)

getTkProgressBar(pb)
setTkProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'tkProgressBar'
close(con, ...)
```

**Arguments**

|                |                                                                                               |
|----------------|-----------------------------------------------------------------------------------------------|
| title, label   | character strings, giving the window title and the label on the dialog box respectively.      |
| min, max       | (finite) numeric values for the extremes of the progress bar.                                 |
| initial, value | initial or new value for the progress bar.                                                    |
| width          | the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame). |
| pb, con        | an object of class "tkProgressBar".                                                           |
| ...            | for consistency with the generic.                                                             |

**Details**

tkProgressBar will display a widget containing a label and progress bar.

setTkProgressBar will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of value will be (silently) ignored.

The progress bar should be closed when finished with.

This will use the ttk::progressbar widget for Tk version 8.5 or later, otherwise R's copy of BWidget's progressbar.

**Value**

For tkProgressBar an object of class "tkProgressBar".

For getTkProgressBar and setTkProgressBar, a length-one numeric vector giving the previous value (invisibly for setTkProgressBar).

**See Also**

[txtProgressBar](#)

**Examples**

```
pb <- tkProgressBar("test progress bar", "Some information in %",
                    0, 100, 50)
Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
```

```
for(i in u) {  
  Sys.sleep(0.1)  
  info <- sprintf("%d%% done", round(i))  
  setTkProgressBar(pb, i, sprintf("test (%s)", info), info)  
}  
Sys.sleep(5)  
close(pb)
```

---

tkStartGUI

*Tcl/Tk GUI startup*

---

### Description

Starts up the Tcl/Tk GUI

### Usage

tkStartGUI()

### Details

Starts a GUI console implemented via a Tk text widget. This should probably be called at most once per session. Also redefines the file pager (as used by `help()`) to be the Tk pager.

### Note

tkStartGUI() saves its evaluation environment as `.GUIenv`. This means that the user interface elements can be accessed in order to extend the interface. The three main objects are named `Term`, `Menu`, and `Toolbar`, and the various submenus and callback functions can be seen with `ls(envir = .GUIenv)`.

TkWidgetcmds

*Tk widget commands*

---

### Description

These functions interface to Tk widget commands.

**Usage**

```
tkactivate(widget, ...)
tkadd(widget, ...)
tkaddtag(widget, ...)
tkbbox(widget, ...)
tkcanvasx(widget, ...)
tkcanvasy(widget, ...)
tkcget(widget, ...)
tkcompare(widget, ...)
tkconfigure(widget, ...)
tkcoords(widget, ...)
tkcreate(widget, ...)
tkcurselection(widget, ...)
tkdchars(widget, ...)
tkdebug(widget, ...)
tkdelete(widget, ...)
tkdelta(widget, ...)
tkdeselect(widget, ...)
tkdlineinfo(widget, ...)
tkdtag(widget, ...)
tkdump(widget, ...)
tkentrycget(widget, ...)
tkentryconfigure(widget, ...)
tkfind(widget, ...)
tkflash(widget, ...)
tkfraction(widget, ...)
tkget(widget, ...)
tkgettags(widget, ...)
tkicursor(widget, ...)
tkidentify(widget, ...)
tkindex(widget, ...)
tkinsert(widget, ...)
tkinvoke(widget, ...)
tkitembind(widget, ...)
tkitemcget(widget, ...)
tkitemconfigure(widget, ...)
tkitemfocus(widget, ...)
tkitemlower(widget, ...)
tkitemraise(widget, ...)
tkitemscale(widget, ...)
tkmark.gravity(widget, ...)
tkmark.names(widget, ...)
tkmark.next(widget, ...)
tkmark.previous(widget, ...)
tkmark.set(widget, ...)
tkmark.unset(widget, ...)
tkmove(widget, ...)
tknearest(widget, ...)
```

```
tkpost(widget, ...)
tkpostcascade(widget, ...)
tkpostscript(widget, ...)
tkscan.mark(widget, ...)
tkscan.dragto(widget, ...)
tksearch(widget, ...)
tksee(widget, ...)
tkselect(widget, ...)
tkselection.adjust(widget, ...)
tkselection.anchor(widget, ...)
tkselection.clear(widget, ...)
tkselection.from(widget, ...)
tkselection.includes(widget, ...)
tkselection.present(widget, ...)
tkselection.range(widget, ...)
tkselection.set(widget, ...)
tkselection.to(widget, ...)
tkset(widget, ...)
tksize(widget, ...)
tktoggle(widget, ...)
tktag.add(widget, ...)
tktag.bind(widget, ...)
tktag.cget(widget, ...)
tktag.configure(widget, ...)
tktag.delete(widget, ...)
tktag.lower(widget, ...)
tktag.names(widget, ...)
tktag.nextrange(widget, ...)
tktag.prevrange(widget, ...)
tktag.raise(widget, ...)
tktag.ranges(widget, ...)
tktag.remove(widget, ...)
tktype(widget, ...)
tkunpost(widget, ...)
tkwindow.cget(widget, ...)
tkwindow.configure(widget, ...)
tkwindow.create(widget, ...)
tkwindow.names(widget, ...)
tkxview(widget, ...)
tkxview.moveto(widget, ...)
tkxview.scroll(widget, ...)
tkyposition(widget, ...)
tkyview(widget, ...)
tkyview.moveto(widget, ...)
tkyview.scroll(widget, ...)
```

**Arguments**

|        |                            |
|--------|----------------------------|
| widget | The widget this applies to |
|--------|----------------------------|

...                      Handled via `.Tcl.args`

### Details

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. Except for a few exceptions, the pattern is that Tcl widget commands possibly with subcommands like `.a.b selection clear` are converted to function names like `tkselection.clear` and the widget is given as the first argument.

```
## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tkoplevel()
tkpack(txt.w <- tktext(tt))
tkinsert(txt.w, "0.0", "plot(1:10)")

# callback function
eval.txt <- function()
  eval(parse(text = tclvalue(tkget(txt.w, "0.0", "end"))))
tkpack(but.w <- tkbutton(tt, text = "Submit", command = eval.txt))

## Try pressing the button, edit the text and when finished:

tkdestroy(tt)

## End(Not run)
```

---

TkWidgets

*Tk widgets*

---

### Description

Create Tk widgets and associated R objects.

### Usage

```
tkwidget(parent, type, ...)

tkbutton(parent, ...)
tkcanvas(parent, ...)
tkcheckboxbutton(parent, ...)
```

```
tkentry(parent, ...)
ttkentry(parent, ...)
tkframe(parent, ...)
tklabel(parent, ...)
tklistbox(parent, ...)
tkmenu(parent, ...)
tkmenubutton(parent, ...)
tkmessage(parent, ...)
tkradiobutton(parent, ...)
tkscale(parent, ...)
tkscrollbar(parent, ...)
tktext(parent, ...)
tktoplevel(parent = .TkRoot, ...)
```

```
ttkbutton(parent, ...)
ttkcheckbutton(parent, ...)
ttkcombobox(parent, ...)
ttkframe(parent, ...)

### Arguments

|        |                                               |
|--------|-----------------------------------------------|
| parent | Parent of widget window.                      |
| type   | string describing the type of widget desired. |
| ...    | handled via <a href="#">.Tcl.args</a> .       |

### Details

These functions create Tk widgets. `tkwidget` creates a widget of a given type, the others simply call `tkwidget` with the respective type argument.

The functions starting `ttk` are for the themed widget set for Tk 8.5 or later. A tutorial can be found at <http://www.tkdocs.com>.

It is not possible to describe the widgets and their arguments in full. Please refer to the Tcl/Tk documentation.

**See Also**

[TclInterface](#), [TkCommands](#), [TkWidgetcmds](#)

**Examples**

```
## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
label.widget <- tklabel(tt, text = "Hello, World!")
button.widget <- tkbutton(tt, text = "Push",
                          command = function()cat("OW!\n"))
tkpack(label.widget, button.widget) # geometry manager
                                   # see Tk-commands

## Push the button and then...

tkdestroy(tt)

## test for themed widgets
if(as.character(tcl("info", "tclversion")) >= "8.5") {
  # make use of themed widgets
  # list themes
  as.character(tcl("ttk::style", "theme", "names"))
  # select a theme -- here pre-XP windows
  tcl("ttk::style", "theme", "use", "winnative")
} else {
  # use Tk 8.0 widgets
}

## End(Not run)
```

---

tk\_choose.dir

*Choose a Folder Interactively*

---

**Description**

Use a Tk widget to choose a directory interactively.

**Usage**

```
tk_choose.dir(default = "", caption = "Select directory")
```

**Arguments**

|         |                                      |
|---------|--------------------------------------|
| default | which directory to show initially.   |
| caption | the caption on the selection dialog. |

**Value**

A length-one character vector, character NA if ‘Cancel’ was selected.

**See Also**

[tk\\_choose.files](#)

**Examples**

```
## Not run:
tk_choose.dir(getwd(), "Choose a suitable folder")

## End(Not run)
```

---

|                 |                                             |
|-----------------|---------------------------------------------|
| tk_choose.files | <i>Choose a List of Files Interactively</i> |
|-----------------|---------------------------------------------|

---

**Description**

Use a Tk file dialog to choose a list of zero or more files interactively.

**Usage**

```
tk_choose.files(default = "", caption = "Select files",
                multi = TRUE, filters = NULL, index = 1)
```

**Arguments**

|         |                                                  |
|---------|--------------------------------------------------|
| default | which filename to show initially.                |
| caption | the caption on the file selection dialog.        |
| multi   | whether to allow multiple files to be selected.  |
| filters | two-column character matrix of filename filters. |
| index   | unused.                                          |

**Details**

Unlike [file.choose](#), tk\_choose.files will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas [file.choose](#) would signal an error.

The format of filters can be seen from the example. File patterns are specified via extensions, with "\*" meaning any file, and "" any file without an extension (a filename not containing a period). (Other forms may work on specific platforms.) Note that the way to have multiple extensions for one file type is to have multiple rows with the same name in the first column, and that whether the extensions are named in file chooser widget is platform-specific. **The format may change before release.**

**Value**

A character vector giving zero or more file paths.

**Note**

A bug in Tk 8.5.0–8.5.4 prevented multiple selections being used.

**See Also**

[file.choose](#), [tk\\_choose.dir](#)

**Examples**

```
Filters <- matrix(c("R code", ".R", "R code", ".s",
                  "Text", ".txt", "All files", "*"),
                4, 2, byrow = TRUE)

Filters
if(interactive()) tk_choose.files(filter = Filters)
```

---

|               |                       |
|---------------|-----------------------|
| tk_messageBox | <i>Tk Message Box</i> |
|---------------|-----------------------|

---

**Description**

An implementation of a generic message box using Tk

**Usage**

```
tk_messageBox(type = c("ok", "okcancel", "yesno", "yesnocancel",
                      "retrycancel", "aburtretrycancel"),
             message, caption = "", default = "", ...)
```

**Arguments**

- type            character. The type of dialog box. It will have the buttons implied by its name. Can be abbreviated.
- message        character. The information field of the dialog box.
- caption        the caption on the widget displayed.
- default        character. The name of the button to be used as the default.
- ...            additional named arguments to be passed to the Tk function of this name. An example is icon = "warning".

**Value**

A character string giving the name of the button pressed.

**See Also**

[tkmessageBox](#) for a 'raw' interface.

---

|                |                          |
|----------------|--------------------------|
| tk_select.list | Select Items from a List |
|----------------|--------------------------|

---

### Description

Select item(s) from a character vector using a Tk listbox.

### Usage

```
tk_select.list(choices, preselect = NULL, multiple = FALSE,  
              title = NULL)
```

### Arguments

|           |                                                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------|
| choices   | a character vector of items.                                                                                          |
| preselect | a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially. |
| multiple  | logical: can more than one item be selected?                                                                          |
| title     | optional character string for window title, or NULL for no title.                                                     |

### Details

This is a version of [select.list](#) implemented as a Tk list box plus OK and Cancel buttons. There will be a scrollbar if the list is too long to fit comfortably on the screen.

The dialog box is *modal*, so a selection must be made or cancelled before the R session can proceed. Double-clicking on an item is equivalent to selecting it and then clicking OK.

If Tk is version 8.5 or later, themed widgets will be used.

### Value

A character vector of selected items. If `multiple` is false and no item was selected (or Cancel was used), "" is returned. If `multiple` is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

### See Also

[select.list](#) (a text version except on Windows and the OS X GUI), [menu](#) (whose `graphics = TRUE` mode uses this on most Unix-alikes).

## Chapter 13

# The tools package

---

|               |                                      |
|---------------|--------------------------------------|
| tools-package | <i>Tools for Package Development</i> |
|---------------|--------------------------------------|

---

### Description

Tools for package development, administration and documentation.

### Details

This package contains tools for manipulating R packages and their documentation.

For a complete list of functions, use `library(help = "tools")`.

### Author(s)

Kurt Hornik and Friedrich Leisch

Maintainer: R Core Team <R-core@r-project.org>

---

|                   |                           |
|-------------------|---------------------------|
| .print.via.format | <i>Printing Utilities</i> |
|-------------------|---------------------------|

---

### Description

`.print.via.format` is a “prototype” `print()` method, useful, at least as a start, by a simple

```
print.<myS3class> <- .print.via.format
```

### Usage

```
.print.via.format(x, ...)
```

**Arguments**

`x` object to be printed.

`...` optional further arguments, passed to `format`.

**Value**

`x`, invisibly (by `invisible()`), as `print` methods should.

**See Also**

The `print` generic; its default method `print.default` (used for many basic implicit classes such as "numeric", "character" and `arrays` of them, `lists` etc).

**Examples**

```
## The function is simply defined as
function (x, ...) {
  writeLines(format(x, ...))
  invisible(x)
}

## is used for simple print methods in R, and as prototype for new methods.
```

---

add\_datalist

---

Add a 'datalist' File to a Package

---

**Description**

The `data()` command with no arguments lists all the datasets available via data in attached packages, and to do so a per-package list is installed. Creating that list at install time can be slow for packages with huge datasets, and can be expedited by a supplying 'data/datalist' file.

**Usage**

```
add_datalist(pkgpath, force = FALSE)
```

**Arguments**

`pkgpath` The path to a (source) package.

`force` logical: can an existing 'data/datalist' file be over-written?

**Details**

R CMD build will call this function to add a data list to packages with 1MB or more of data.

It is also helpful to give a 'data/datalist' file in packages whose datasets have many dependencies, including loading the packages itself (and maybe others).

**See Also**

[data](#).

The ‘Writing R Extensions’ manual.

---

 assertCondition

*Asserting Error Conditions*

---

**Description**

When testing code, it is not sufficient to check that results are correct, but also that errors or warnings are signalled in appropriate situations. The functions described here provide a convenient facility for doing so. The three functions check that evaluating the supplied expression produces an error, a warning or one of a specified list of conditions, respectively. If the assertion fails, an error is signalled.

**Usage**

```
assertError(expr, verbose = FALSE)
assertWarning(expr, verbose = FALSE)
assertCondition(expr, ..., .exprString = , verbose = FALSE)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>expr</code>        | an unevaluated R expression which will be evaluated via <a href="#">tryCatch</a> ( <code>expr</code> , <code>...</code> ).                                                                                                                                                                                                                                                       |
| <code>...</code>         | <a href="#">character</a> strings corresponding to the classes of the conditions that would satisfy the assertion; e.g., "error" or "warning". If none are specified, any condition will satisfy the assertion. See the details section.                                                                                                                                         |
| <code>.exprString</code> | The string to be printed corresponding to <code>expr</code> . By default, the actual <code>expr</code> will be deparsed. Will be omitted if the function is supplied with the actual expression to be tested. If <code>assertCondition()</code> is called from another function, with the actual expression passed as an argument to that function, supply the deparsed version. |
| <code>verbose</code>     | If TRUE, a message is printed when the condition is satisfied.                                                                                                                                                                                                                                                                                                                   |

**Details**

`assertCondition()` uses the general condition mechanism to check all the conditions generated in evaluating `expr`. The occurrence of any of the supplied condition classes among these satisfies the assertion regardless of what other conditions may be signalled.

`assertError()` is a convenience function for asserting errors; it calls `assertCondition()`.

`assertWarning()` asserts that a warning will be signalled, but *not* an error, whereas `assertCondition(expr, "warning")` will be satisfied even if an error follows the warning. See the examples.

**Value**

If the assertion is satisfied, a list of all the condition objects signalled is returned, invisibly. See [conditionMessage](#) for the interpretation of these objects. Note that *all* conditions signalled during the evaluation are returned, whether or not they were among the requirements.

**Author(s)**

John Chambers and Martin Maechler

**See Also**

[stop](#), [warning](#); [signalCondition](#), [tryCatch](#).

**Examples**

```

assertError(sqrt("abc"))
assertWarning(matrix(1:8, 4,3))

assertCondition( ""-1 ) # ok, any condition would satisfy this

try( assertCondition(sqrt(2), "warning") )
## .. Failed to get warning in evaluating sqrt(2)
  assertCondition(sqrt("abc"), "error") # ok
try( assertCondition(sqrt("abc"), "warning") )# -> error: had no warning
  assertCondition(sqrt("abc"), "error")
## identical to assertError() call above

assertCondition(matrix(1:5, 2,3), "warning")
try( assertCondition(matrix(1:8, 4,3), "error") )
## .. Failed to get expected error ....

## either warning or worse:
assertCondition(matrix(1:8, 4,3), "error","warning") # OK
assertCondition(matrix(1:8, 4, 3), "warning") # OK

## when both are signalled:
ff <- function() { warning("my warning"); stop("my error") }
  assertCondition(ff(), "warning")
## but assertWarning does not allow an error to follow
try(assertWarning(ff()))
  assertCondition(ff(), "error") # ok
assertCondition(ff(), "error", "warning") # ok (quietly, catching warning)

## assert that assertC..() does not assert [and use *one* argument only]
assertCondition( assertCondition(sqrt( 2 ), "warning") )
assertCondition( assertCondition(sqrt("abc"), "warning"), "error")
assertCondition( assertCondition(matrix(1:8, 4,3), "error"),
  "error")

```

---

|          |                                               |
|----------|-----------------------------------------------|
| bibstyle | <i>Select or define a bibliography style.</i> |
|----------|-----------------------------------------------|

---

## Description

This function defines and registers styles for rendering [bibentry](#) objects into ‘Rd’ format, for later conversion to text, HTML, etc.

## Usage

```
bibstyle(style, envir, ..., .init = FALSE, .default = TRUE)
getBibstyle(all = FALSE)
```

## Arguments

|          |                                                                         |
|----------|-------------------------------------------------------------------------|
| style    | A character string naming the style.                                    |
| envir    | (optional) An environment holding the functions to implement the style. |
| ...      | Named arguments to add to the environment.                              |
| .init    | Whether to initialize the environment from the default style "JSS".     |
| .default | Whether to set the specified style as the default style.                |
| all      | Whether to return the names of all registered styles.                   |

## Details

Rendering of [bibentry](#) objects may be done using routines modelled after those used by BibTeX. This function allows environments to be created and manipulated to contain those routines.

There are two ways to create a new style environment. The easiest is to set `.init = TRUE`, in which case the environment will be initialized with a copy of the default "JSS" environment. (This style is modelled after the ‘jss.bst’ style used by the *Journal of Statistical Software*.) Alternatively, the `envir` argument can be used to specify a completely new style environment.

To find the name of the default style, use `getBibstyle()`. To retrieve an existing style without setting it as the default, use `bibstyle(style, .default = FALSE)`. To modify an existing style, specify style and some named entries via `...` (Modifying the default "JSS" style is discouraged.) Setting style to NULL or leaving it missing will retrieve the default style, but modifications will not be allowed.

At a minimum, the environment should contain routines to render each of the 12 types of bibliographic entry supported by [bibentry](#) as well as several other routines described below. The former must be named `formatArticle`, `formatBook`, `formatInbook`, `formatIncollection`, `formatInproceedings`, `formatManual`, `formatMastersthesis`, `formatMisc`, `formatPhdthesis`, `formatProceedings`, `formatTechreport` and `formatUnpublished`. Each of these takes one argument, a single [unclass](#)’ed entry from the [bibentry](#) vector passed to the renderer, and should produce a single element character vector (possibly containing newlines).

The other routines are as follows. `sortKeys`, a function to produce a sort key to sort the entries, is passed the original [bibentry](#) vector and should produce a sortable vector of the same length to

define the sort order. Finally, the optional function `cite` should have the same argument list as `utils::cite`, and should produce a citation to be used in text.

The `format` method for "bibentry" objects adds a field named `".index"` to each entry after sorting and before formatting. This is a 1-based index within the complete object that can be used in styles that require numbering. Although the "JSS" style doesn't use numbers, it includes a `fmtPrefix()` stub function that may be used to display them. See the example below.

## Value

`bibstyle` returns the environment which has been selected or created.

`getBibstyle` returns the name of the default style, or all style names.

| latex    | logical; <a href="#">texi2pdf</a> be run if weaving produces a ‘.tex’ file?                                             |
| tangle   | logical; should tangle be run?                                                                                          |
| quiet    | logical; run in quiet mode?                                                                                             |
| clean    | logical; whether to remove some newly created, often intermediate, files. See details below.                            |
| keep     | a list of file names to keep in any case when cleaning. Note that “target” files are kept anyway.                       |
| engine   | NULL or character; name of vignette engine to use. Overrides any <code>\VignetteEngine{}</code> markup in the vignette. |
| buildPkg | NULL or character; an optional package in which to find the vignette engine.                                            |
| encoding | the encoding to assume for the file. If not specified, it will be inferred from the file contents.                      |
| ...      | Additional arguments passed to weave and tangle.                                                                        |

## Details

This function determines the vignette engine for the vignette (default `utils::Sweave`), then weaves and/or tangles the vignette using that engine. Finally, if `clean` is `TRUE`, newly created intermediate files (non “targets”, where these depend on the engine, etc, and not any in `keep`) will be deleted. If `clean` is `NA`, and `weave` is true, newly created intermediate output files (e.g., ‘.tex’) will not be deleted even if a ‘.pdf’ file has been produced from them.

If `buildPkg` is specified, it will be loaded before the vignette is processed, and will be used as the default package in the search for a vignette engine, but an explicitly specified package in the vignette source (e.g., using `\VignetteEngine{utils::Sweave}` to specify the Sweave engine in the **utils** package) will override it. In contrast, if the engine argument is given, it will override the vignette source.

### Value

A character vector naming the files that have been produced.

### Author(s)

Henrik Bengtsson and Duncan Murdoch

### See Also

[buildVignettes](#) for building all vignettes in a package.

---

|                |                                         |
|----------------|-----------------------------------------|
| buildVignettes | <i>List and Build Package Vignettes</i> |
|----------------|-----------------------------------------|

---

### Description

Run [Sweave](#) (or other custom weave function) and [texi2dvi](#) on all vignettes of a package.

### Usage

```
buildVignettes(package, dir, lib.loc = NULL, quiet = TRUE,
               clean = TRUE, tangle = FALSE)
```

```
pkgVignettes(package, dir, subdirs = NULL, lib.loc = NULL,
              output = FALSE, source = FALSE, check = FALSE)
```

### Arguments

|         |                                                                                                                                                                                                    |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string naming an installed package. If given, vignette source files are by default looked for in subdirectory ‘doc’.                                                                   |
| dir     | a character string specifying the path to a package’s root source directory. This subdirectory ‘vignettes’ (or if it does not exist ‘inst/doc’) is searched for vignette source files.             |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package. |
| quiet   | logical. Weave and run <a href="#">texi2pdf</a> in quiet mode.                                                                                                                                     |
| clean   | Remove all files generated by the build, even if there were copies there before.                                                                                                                   |
| tangle  | logical. Do tangling as well as weaving.                                                                                                                                                           |

|         |                                                                                                                                                                                                                                                          |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| subdirs | a character vector of subdirectories of <code>dir</code> in which to look for vignettes. The first which exists is used. Defaults to "doc" if package is supplied, otherwise "vignettes".                                                                |
| output  | logical indicating if the output filenames for each vignette should be returned (in component outputs).                                                                                                                                                  |
| source  | logical indicating if the <i>tangled</i> output filenames for each vignette should be returned (in component sources).                                                                                                                                   |
| check   | logical. If TRUE, check whether all files that have vignette-like filenames have an identifiable vignette engine. This may be a false positive if a file is not a vignette but has a filename matching a pattern defined by one of the vignette engines. |

Details

`buildVignettes` is used by `R CMD build` and `R CMD check` to (re-)build vignette PDFs from their sources.

Value

`buildVignettes` is called for its side effect of creating the PDF versions of all vignettes, and if `tangle = TRUE`, extracting the R code.

`pkgVignettes` returns an object of class "pkgVignettes" if a vignette directory is found, otherwise NULL.

Examples

```
gVigns <- pkgVignettes("grid")
str(gVigns)
```

---

|          |                                                 |
|----------|-------------------------------------------------|
| charsets | <i>Conversion Tables between Character Sets</i> |
|----------|-------------------------------------------------|

---

Description

`charset_to_Unicode` is a matrix of Unicode code points with columns for the common 8-bit encodings.

`Adobe_glyphs` is a data frame which gives Adobe glyph names for Unicode code points. It has two character columns, "adobe" and "unicode" (a 4-digit hex representation).

Usage

```
charset_to_Unicode

Adobe_glyphs
```

## Details

charset\_to\_Unicode is an integer matrix of class `c("noquote", "hexmode")` so prints in hexadecimal. The mappings are those used by libiconv: there are differences in the way quotes and minus/hyphen are mapped between sources (and the postscript encoding files use a different mapping).

Adobe\_glyphs includes all the Adobe glyph names which correspond to single Unicode characters. It is sorted by Unicode code point and within a point alphabetically on the glyph (there can be more than one name for a Unicode code point). The data are in the file '[R\\_HOME/share/encodings/Adobe\\_glyphlist](#)'.

## Source

<https://partners.adobe.com/public/developer/en/opentype/glyphlist.txt>

## Examples

```
## find Adobe names for ISOLatin2 chars.
latin2 <- charset_to_Unicode[, "ISOLatin2"]
aUnicode <- as.numeric(paste0("0x", Adobe_glyphs$unicode))
keep <- aUnicode %in% latin2
aUnicode <- aUnicode[keep]
aAdobe <- Adobe_glyphs[keep, 1]
## first match
aLatin2 <- aAdobe[match(latin2, aUnicode)]
## all matches
bLatin2 <- lapply(1:256, function(x) aAdobe[aUnicode == latin2[x]])
format(bLatin2, justify = "none")
```

---

checkFF

*Check Foreign Function Calls*

---

## Description

Performs checks on calls to compiled code from R code. Currently only checks whether the interface functions such as `.C` and `.Fortran` are called with a "[NativeSymbolInfo](#)" first argument or with argument `PACKAGE` specified, which is highly recommended to avoid name clashes in foreign function calls.

## Usage

```
checkFF(package, dir, file, lib.loc = NULL,
         registration = FALSE, check_DUP = FALSE,
         verbose = getOption("verbose"))
```

### Arguments

|              |                                                                                                                                                                                                    |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package      | a character string naming an installed package. If given, the installed R code of the package is checked.                                                                                          |
| dir          | a character string specifying the path to a package's root source directory. This should contain the subdirectory 'R' (for R code). Only used if package is not given.                             |
| file         | the name of a file containing R code to be checked. Used if neither package nor dir are given.                                                                                                     |
| lib.loc      | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package. |
| registration | a logical. If TRUE, checks the registration information on the call (if available).                                                                                                                |
| check_DUP    | a logical. If TRUE, .C and .Fortran calls with DUP = FALSE are reported.                                                                                                                           |
| verbose      | a logical. If TRUE, additional diagnostics are printed (and the result is returned invisibly).                                                                                                     |

### Details

Note that we can only check if the name argument is a symbol or a character string, not what class of object the symbol resolves to at run-time.

If the package has a namespace which contains a `useDynLib` directive, calls in top-level functions in the package are not reported as their symbols will be preferentially looked up in the DLL named in the first `useDynLib` directive.

This checks that calls with `PACKAGE` specified are to the same package, and reports separately those which are in base packages and those which are in other packages (and if those packages are specified in the 'DESCRIPTION' file).

### Value

An object of class "checkFF".

There are `format` and `print` methods to display the information contained in such objects.

### See Also

`.C`, `.Fortran`; `Foreign`.

### Examples

```
# order is pretty much random
checkFF(package = "stats", verbose = TRUE)
```

---

`checkMD5sums`*Check and Create MD5 Checksum Files*

---

**Description**

`checkMD5sums` checks the files against a file ‘MD5’.

**Usage**

```
checkMD5sums(package, dir)
```

**Arguments**

|                      |                                                              |
|----------------------|--------------------------------------------------------------|
| <code>package</code> | the name of an installed package                             |
| <code>dir</code>     | the path to the top-level directory of an installed package. |

**Details**

The file ‘MD5’ which is created is in a format which can be checked by `md5sum -c MD5` if a suitable command-line version of `md5sum` is available. (For Windows, one is supplied in the bundle at <https://cran.r-project.org/bin/windows/Rtools>.)

If `dir` is missing, an installed package of name `package` is searched for.

The private function `tools:::installMD5sums` is used to create MD5 files in the Windows build.

**Value**

`checkMD5sums` returns a logical, NA if there is no ‘MD5’ file to be checked.

**See Also**

[md5sum](#)

---

`checkPoFiles`*Check translation files for inconsistent format strings.*

---

**Description**

These functions compare formats embedded in English messages with translated strings to check for consistency. `checkPoFile` checks one file, while `checkPoFiles` checks all files for a specified language.

**Usage**

```
checkPoFile(f, strictPlural = FALSE)
checkPoFiles(language, dir = ".")
```

### Arguments

|                           |                                                                          |
|---------------------------|--------------------------------------------------------------------------|
| <code>f</code>            | a character string giving a single filepath.                             |
| <code>strictPlural</code> | whether to compare formats of singular and plural forms in a strict way. |
| <code>language</code>     | a character string giving a language code.                               |
| <code>dir</code>          | a path to a directory in which to check files.                           |

### Details

Part of R's internationalization depends on translations of messages in '.po' files. In these files an 'English' message taken from the R sources is followed by a translation into another language. Many of these messages are format strings for C or R `sprintf` and related functions. In these cases, the translation must give a compatible format or an error will be generated when the message is displayed.

The rules for compatibility differ between C and R in several ways. C supports several conversions not supported by R, namely c, u, p, n. It is allowed in C's `sprintf()` function to have more arguments than are needed by the format string, but in R the counts must match exactly. R requires types of arguments to match, whereas C will do the display whether it makes sense or not.

These functions compromise on the testing as follows. The additional formats allowed in C are accepted, and all differences in argument type or count are reported. As a consequence some reported differences are not errors.

If the `strictPlural` argument is TRUE, then argument lists must agree exactly between singular and plural forms of messages; if FALSE, then translations only need to match one or the other of the two forms. When `checkPoFiles` calls `checkPoFile`, the `strictPlural` argument is set to TRUE for files with names starting 'R-', and to FALSE otherwise.

Items marked as 'fuzzy' in the '.po' file are not processed (as they are ignored by the message compiler).

If a difference is found, the translated string is checked for variant percent signs (e.g., the wide percent sign "\uFF05"). Such signs will not be recognized as format specifiers, and are likely to be errors.

### Value

Both functions return an object of S3 class "check\_po\_files". A `print` method is defined for this class to display a report on the differences.

### Author(s)

Duncan Murdoch

### References

See the GNU gettext manual for the '.po' file format:

```
## Not run:
checkPoFiles("de", "/path/to/R/src/directory")

## End(Not run)
```

checkRd

*Check an Rd Object***Description**

Check an help file or the output of the [parse\\_Rd](#) function.

**Usage**

```
checkRd(Rd, defines = .Platform$OS.type, stages = "render",
        unknownOK = TRUE, listOK = TRUE, ..., def_enc = FALSE)
```

**Arguments**

|           |                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------|
| Rd        | a filename or Rd object to use as input.                                                                                 |
| defines   | string(s) to use in #ifdef tests.                                                                                        |
| stages    | at which stage ("build", "install", or "render") should \Sexpr macros be executed? See the notes below.                  |
| unknownOK | unrecognized macros are treated as errors if FALSE, otherwise warnings.                                                  |
| listOK    | unnecessary non-empty braces (e.g., around text, not as an argument) are treated as errors if FALSE, otherwise warnings. |
| ...       | additional parameters to pass to <a href="#">parse_Rd</a> when Rd is a filename. One that is often useful is encoding.   |
| def_enc   | logical: has the package declared an encoding, so tests for non-ASCII text are suppressed?                               |

**Details**

checkRd performs consistency checks on an Rd file, confirming that required sections are present, etc.

It accepts a filename for an Rd file, and will use [parse\\_Rd](#) to parse it before applying the checks. If so, warnings from parse\_Rd are collected, together with those from the internal function prepare\_Rd, which does the #ifdef and \Sexpr processing, drops sections that would not be rendered or are duplicated (and should not be) and removes empty sections.

An Rd object is passed through prepare\_Rd, but it may already have been (and installed Rd objects have).

Warnings are given a 'level': those from prepare\_Rd have level 0. These include

All text must be in a section

Only one *tag name* section is allowed: the first will be used  
 Section *name* is unrecognized and will be dropped  
 Dropping empty section *name*

checkRd itself can show

```

7 Tag tag name not recognized
7 \tabular format must be simple text
7 Unrecognized \tabular format: ...
7 Only n columns allowed in this table
7 Must have a tag name
7 Only one tag name is allowed
7 Tag tag name must not be empty
7 \docType must be plain text
5 Tag \method is only valid in \usage
5 Tag \dontrun is only valid in \examples
5 Tag tag name is invalid in a block name block
5 Title of \section must be non-empty plain text
5 \title content must be plain text
3 Empty section tag name
-1 Non-ASCII contents without declared encoding
-1 Non-ASCII contents in second part of \enc
-3 Tag ... is not valid in a code block
-3 Apparent non-ASCII contents without declared encoding
-3 Apparent non-ASCII contents in second part of \enc
-3 Unnecessary braces at ...
-3 \method not valid outside a code block
```

and variations with `\method` replaced by `\S3method` or `\S4method`.

Note that both `prepare_Rd` and `checkRd` have tests for an empty section: that in `checkRd` is stricter (essentially that nothing is output).

## Value

This may fail through an R error, but otherwise warnings are collected as returned as an object of class "checkRd", a character vector of messages. This class has a `print` method which only prints unique messages, and has argument `minlevel` that can be used to select only more serious messages. (This is set to -1 in R CMD check.)

Possible fatal errors are those from running the parser (e.g., a non-existent file, unclosed quoted string, non-ASCII input without a specified encoding) or from `prepare_Rd` (multiple `\Rdversion` declarations, invalid `\encoding` or `\docType` or `\name` sections, and missing or duplicate `\name` or `\title` sections).

|               |                                                           |
|---------------|-----------------------------------------------------------|
| checkRdaFiles | <i>Report on Details of Saved Images or Re-saves them</i> |
|---------------|-----------------------------------------------------------|

---

Description

This reports for each of the files produced by `save` the size, if it was saved in ASCII or XDR binary format, and if it was compressed (and if so in what format).  
Usually such files have extension `‘.rda’` or `‘.RData’`, hence the name of the function.

Usage

```
checkRdaFiles(paths)
resaveRdaFiles(paths, compress = c("auto", "gzip", "bzip2", "xz"),
               compression_level)
```

Arguments

|                                                        |                                                                                                                                                                                     |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>paths</code>                                     | A character vector of paths to save files. If this specifies a single directory, it is taken to refer to all <code>‘.rda’</code> and <code>‘.RData’</code> files in that directory. |
| <code>compress</code> , <code>compression_level</code> | type and level of compression: see <a href="#">save</a> . Values of <code>compress</code> can be abbreviated.                                                                       |

Details

`compress = "auto"` asks `R` to choose the compression and ignores `compression_level`. It will try `"gzip"`, `"bzip2"` and if the `"gzip"` compressed size is over 10Kb, `"xz"` and choose the smallest compressed file (but with a 10% bias towards `"gzip"`). This can be slow.

Value

For `checkRdaFiles`, a data frame with rows names `paths` and columns

|                       |                                                                                                                                                                                                                                                                |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>size</code>     | numeric: file size in bytes, NA if the file does not exist.                                                                                                                                                                                                    |
| <code>ASCII</code>    | logical: true for <code>save(ASCII = TRUE)</code> , NA if the format is not that of an <code>R</code> save file.                                                                                                                                               |
| <code>compress</code> | character: type of compression. One of <code>"gzip"</code> , <code>"bzip2"</code> , <code>"xz"</code> , <code>"none"</code> or <code>"unknown"</code> (which means that if this is an <code>R</code> save file it is from a later version of <code>R</code> ). |
| <code>version</code>  | integer: the version of the save – usually 2 but 1 for very old files, and NA for other files.                                                                                                                                                                 |

## Examples

```
## Not run:
## from a package top-level source directory
paths <- sort(Sys.glob(c("data/*.rda", "data/*.RData")))
(res <- checkRdaFiles(paths))
## pick out some that may need attention
bad <- is.na(res$ASCII) | res$ASCII | (res$size > 1e4 & res$compress == "none")
res[bad, ]

## End(Not run)
```

---

checkTnF

---

*Check R Packages or Code for T/F*

---

## Description

Checks the specified R package or code file for occurrences of T or F, and gathers the expression containing these. This is useful as in R T and F are just variables which are set to the logicals TRUE and FALSE by default, but are not reserved words and hence can be overwritten by the user. Hence, one should always use TRUE and FALSE for the logicals.

## Usage

```
checkTnF(package, dir, file, lib.loc = NULL)
```

## Arguments

|         |                                                                                                                                                                                                                                                                                                            |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string naming an installed package. If given, the installed R code and the examples in the documentation files of the package are checked. R code installed as an image file cannot be checked.                                                                                                |
| dir     | a character string specifying the path to a package's root source directory. This must contain the subdirectory 'R' (for R code), and should also contain 'man' (for documentation). Only used if package is not given. If used, the R code files and the examples in the documentation files are checked. |
| file    | the name of a file containing R code to be checked. Used if neither package nor dir are given.                                                                                                                                                                                                             |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                                                                                                         |

## Value

An object of class "checkTnF" which is a list containing, for each file where occurrences of T or F were found, a list with the expressions containing these occurrences. The names of the list are the corresponding file names.

There is a print method for nicely displaying the information contained in such objects.

---

|                |                                |
|----------------|--------------------------------|
| checkVignettes | <i>Check Package Vignettes</i> |
|----------------|--------------------------------|

---

### Description

Check all [Sweave](#) files of a package by running [Sweave](#) and/or [Stangle](#) on them. All R source code files found after the tangling step are [sourced](#) to check whether all code can be executed without errors.

### Usage

```
checkVignettes(package, dir, lib.loc = NULL,
               tangle = TRUE, weave = TRUE, latex = FALSE,
               workdir = c("tmp", "src", "cur"),
               keepfiles = FALSE)
```

### Arguments

|           |                                                                                                                                                                                                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package   | a character string naming an installed package. If given, Sweave files are searched in subdirectory 'doc'.                                                                                                                                                            |
| dir       | a character string specifying the path to a package's root source directory. This subdirectory 'inst/doc' is searched for Sweave files.                                                                                                                               |
| lib.loc   | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                                                                    |
| tangle    | Perform a tangle and <a href="#">source</a> the extracted code?                                                                                                                                                                                                       |
| weave     | Perform a weave?                                                                                                                                                                                                                                                      |
| latex     | logical: if weave and latex are TRUE and there is no 'Makefile' in the vignettes directory, run the weaved files through pdf <sub>l</sub> atex.                                                                                                                       |
| workdir   | Directory used as working directory while checking the vignettes. If "tmp" then a temporary directory is created, this is the default. If "src" then the directory containing the vignettes itself is used, if "cur" then the current working directory of R is used. |
| keepfiles | Delete files in the temporary directory? This option is ignored when workdir != "tmp".                                                                                                                                                                                |

### Details

A 'vignette' is a file in the package's 'inst/doc' directory with extension '.Rnw' (preferred), '.Snw', '.Rtex' or '.Stex' (and lower-case versions are also accepted).

If tangle is true, this function runs [Stangle](#) to produce (one or more) R code files from each vignette, then sources each code file in turn.

If weave is true, the vignettes are run through [Sweave](#), which will produce a '.tex' file for each vignette. If latex is also true, [texi2pdf](#) is run on the '.tex' files from those vignettes which did not give errors in the previous steps.

**Value**

An object of class "checkVignettes", which is a list with the error messages found during the tangle, source, weave and latex steps. There is a print method for displaying the information contained in such objects.

---

check\_packages\_in\_dir *Check Source Packages and Their Reverse Dependencies*

---

**Description**

Check source packages in a given directory, optionally with their reverse dependencies.

**Usage**

```
check_packages_in_dir(dir,
                      check_args = character(),
                      check_args_db = list(),
                      reverse = NULL,
                      check_env = character(),
                      xvfb = FALSE,
                      Ncpus = getOption("Ncpus", 1L),
                      clean = TRUE,
                      ...)

summarize_check_packages_in_dir_results(dir, all = TRUE,
                                       full = FALSE)
summarize_check_packages_in_dir_timings(dir, all = FALSE,
                                       full = FALSE)
summarize_check_packages_in_dir_depends(dir, all = FALSE,
                                       which = c("Depends",
                                                "Imports",
                                                "LinkingTo"))

check_packages_in_dir_changes(dir, old,
                             outputs = FALSE, sources = FALSE)
```

**Arguments**

|               |                                                                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dir           | a character string giving the path to the directory with the source ‘.tar.gz’ files to be checked.                                                                                        |
| check_args    | a character vector with arguments to be passed to R CMD check, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively. |
| check_args_db | a named list of character vectors with arguments to be passed to R CMD check, with names the respective package names.                                                                    |

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| reverse   | a list with names partially matching "repos", "which", or "recursive", giving the repositories to use for locating reverse dependencies (default: <code>getOption("repos")</code> ), the types of reverse dependencies (default: <code>c("Depends", "Imports", "LinkingTo")</code> , with shorthands "most" and "all" as for <a href="#">package_dependencies</a> ), and indicating whether to also check reverse dependencies of reverse dependencies and so on (default: FALSE), or NULL (default), in which case no reverse dependencies are checked. |
| check_env | a character vector of name=value strings to set environment variables for checking, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.                                                                                                                                                                                                                                                                                                                                           |
| xvfb      | a logical indicating whether to perform checking inside a virtual framebuffer X server (Unix only), or a character vector of Xvfb options for doing so.                                                                                                                                                                                                                                                                                                                                                                                                  |
| Ncpus     | the number of parallel processes to use for parallel installation and checking.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| clean     | a logical indicating whether to remove the downloaded reverse dependency sources.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ...       | currently not used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| all       | a logical indicating whether to also summarize the reverse dependencies checked.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| full      | a logical indicating whether to also give details for checks with non-ok results, or summarize check example timings (if available).                                                                                                                                                                                                                                                                                                                                                                                                                     |
| which     | see <a href="#">package_dependencies</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| old       | a character string giving the path to the directory of a previous <code>check_packages_in_dir</code> run.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| outputs   | a logical indicating whether to analyze changes in the outputs of the checks performed, or only (default) the status of the checks.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| sources   | a logical indicating whether to also investigate the changes in the source files checked (default: FALSE).                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Details

`check_packages_in_dir` allows to conveniently check source package `‘.tar.gz’` files in the given directory `dir`, along with their reverse dependencies as controlled by `reverse`.

The "which" component of `reverse` can also be a list, in which case reverse dependencies are obtained for each element of the list and the corresponding element of the "recursive" component of `reverse` (which is recycled as needed).

If needed, the source `‘.tar.gz’` files of the reverse dependencies to be checked as well are downloaded into `dir` (and removed at the end if `clean` is true). Next, all packages (additionally) needed for checking are installed to the `‘Library’` subdirectory of `dir`. Then, all `‘.tar.gz’` files are checked using the given arguments and environment variables, with outputs and messages to files in the `‘Outputs’` subdirectory of `dir`. The `‘*.Rcheck’` directories with the check results of the reverse dependencies are renamed by prefixing their base names with `‘rdepends_’`.

Results and timings can conveniently be summarized using `summarize_check_packages_in_dir_results` and `summarize_check_packages_in_dir_timings`, respectively.

Installation and checking is performed in parallel if Ncpus is greater than one: this will use `mclapply` on Unix and `parLapply` on Windows.

`check_packages_in_dir` returns an object inheriting from class `"check_packages_in_dir"` which has `print` and `summary` methods.

`check_packages_in_dir_changes` allows to analyze the effect of changing (some of) the sources. With `dir` and `old` the paths to the directories with the new and old sources, respectively, and the corresponding check results, possible changes in the check results can conveniently be analyzed as controlled via options outputs and sources.

### Note

This functionality is still experimental: interfaces may change in future versions.

### Examples

```
## Not run:
## Check packages in dir without reverse dependencies:
check_packages_in_dir(dir)
## Check packages in dir and their reverse dependencies using the
## defaults (all repositories in getOption("repos"), all "strong"
## reverse dependencies, no recursive reverse dependencies):
check_packages_in_dir(dir, reverse = list())
## Check packages in dir with their reverse dependencies from CRAN,
## using all strong reverse dependencies and reverse suggests:
check_packages_in_dir(dir,
                      reverse = list(repos = getOption("repos")["CRAN"],
                                     which = "most"))
## Check packages in dir with their reverse dependencies from CRAN,
## using '--as-cran' for the former but not the latter:
check_packages_in_dir(dir,
                      check_args = c("--as-cran", ""),
                      reverse = list(repos = getOption("repos")["CRAN"]))

## End(Not run)
```

### Description

Find inconsistencies between actual and documented ‘structure’ of R objects in a package. `codoc` compares names and optionally also corresponding positions and default values of the arguments of functions. `codocClasses` and `codocData` compare slot names of S4 classes and variable names of data sets, respectively.

**Usage**

```
codoc(package, dir, lib.loc = NULL,
      use.values = NULL, verbose = getOption("verbose"))
codocClasses(package, lib.loc = NULL)
codocData(package, lib.loc = NULL)
```

**Arguments**

|                         |                                                                                                                                                                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code>    | a character string naming an installed package.                                                                                                                                                                                          |
| <code>dir</code>        | a character string specifying the path to a package's root source directory. This must contain the subdirectories 'man' with R documentation sources (in Rd format) and 'R' with R code. Only used if <code>package</code> is not given. |
| <code>lib.loc</code>    | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                                       |
| <code>use.values</code> | if FALSE, do not use function default values when comparing code and docs. Otherwise, compare <i>all</i> default values if TRUE, and only the ones documented in the usage otherwise (default).                                          |
| <code>verbose</code>    | a logical. If TRUE, additional diagnostics are printed.                                                                                                                                                                                  |

**Details**

The purpose of `codoc` is to check whether the documented usage of function objects agrees with their formal arguments as defined in the R code. This is not always straightforward, in particular as the usage information for methods to generic functions often employs the name of the generic rather than the method.

The following algorithm is used. If an installed package is used, it is loaded (unless it is the **base** package), after possibly detaching an already loaded version of the package. Otherwise, if the sources are used, the R code files of the package are collected and sourced in a new environment. Then, the usage sections of the Rd files are extracted and parsed 'as much as possible' to give the formals documented. For interpreted functions in the code environment, the formals are compared between code and documentation according to the values of the argument `use.values`. Synopsis sections are used if present; their occurrence is reported if `verbose` is true.

If a package has a namespace both exported and unexported objects are checked, as well as registered S3 methods. (In the unlikely event of differences the order is exported objects in the package, registered S3 methods and finally objects in the namespace and only the first found is checked.)

Currently, the R documentation format has no high-level markup for the basic 'structure' of classes and data sets (similar to the usage sections for function synopses). Variable names for data frames in documentation objects obtained by suitably editing 'templates' created by `prompt` are recognized by `codocData` and used provided that the documentation object is for a single data frame (i.e., only has one alias). `codocClasses` analogously handles slot names for classes in documentation objects obtained by editing shells created by `promptClass`.

Help files named '*pkgname*-defunct.Rd' for the appropriate *pkgname* are checked more loosely, as they may have undocumented arguments.

**Value**

codoc returns an object of class "codoc". Currently, this is a list which, for each Rd object in the package where an inconsistency was found, contains an element with a list of the mismatches (which in turn are lists with elements code and docs, giving the corresponding arguments obtained from the function's code and documented usage).

codocClasses and codocData return objects of class "codocClasses" and "codocData", respectively, with a structure similar to class "codoc".

There are print methods for nicely displaying the information contained in such objects.

**Note**

The default for use.values has been changed from FALSE to NULL, for R versions 1.9.0 and later.

---

compactPDF

*Compact PDF Files*

---

**Description**

Re-save PDF files (especially vignettes) more compactly. Support function for R CMD build --compact-vignettes.

**Usage**

```
compactPDF(paths,
            qpdf = Sys.which(Sys.getenv("R_QPDF", "qpdf")),
            gs_cmd = Sys.getenv("R_GSCMD", ""),
            gs_quality = Sys.getenv("GS_QUALITY", "none"),
            gs_extras = character())
```

```
## S3 method for class 'compactPDF'
format(x, ratio = 0.9, diff = 1e4, ...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                    |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| paths  | A character vector of paths to PDF files, or a length-one character vector naming a directory, when all '.pdf' files in that directory will be used.                                                                                                               |
| qpdf   | Character string giving the path to the qpdf command. If empty, qpdf will not be used.                                                                                                                                                                             |
| gs_cmd | Character string giving the path to the GhostScript executable, if that is to be used. On Windows this is the path to 'gswin32c.exe' or 'gswin64c.exe'. If "" (the default), the function will try to find a platform-specific path to GhostScript where required. |

|                          |                                                                                                                                                                                         |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>gs_quality</code>  | A character string indicating the quality required: the options are "none" (so GhostScript is not used), "printer" (300dpi), "ebook" (150dpi) and "screen" (72dpi). Can be abbreviated. |
| <code>gs_extras</code>   | An optional character vector of further options to be passed to GhostScript.                                                                                                            |
| <code>x</code>           | An object of class "compactPDF".                                                                                                                                                        |
| <code>ratio, diff</code> | Limits for reporting: files are only reported whose sizes are reduced both by a factor of <code>ratio</code> and by <code>diff</code> bytes.                                            |
| <code>...</code>         | Further arguments to be passed to or from other methods.                                                                                                                                |

### Details

This by default makes use of `qpdf`, available from <http://qpdf.sourceforge.net/> (including as a Windows binary) and included with the CRAN OS X distribution of R. If `gs_cmd` is non-empty and `gs_quality != "none"`, GhostScript will be used first, then `qpdf` if it is available. If `gs_quality != "none"` and `gs_cmd` is "", an attempt will be made to find a GhostScript executable.

`qpdf` and/or `gs_cmd` are run on all PDF files found, and those which are reduced in size by at least 10% and 10Kb are replaced.

The strategy of our use of `qpdf` is to (losslessly) compress both PDF streams and objects. GhostScript compresses streams and more (including downsampling and compressing embedded images) and consequently is much slower and may lose quality (but can also produce much smaller PDF files). However, quality "ebook" is perfectly adequate for screen viewing and printing on laser printers.

Where PDF files are changed they will become PDF version 1.5 files: these have been supported by Acrobat Reader since version 6 in 2003, so this is very unlikely to cause difficulties.

Stream compression is what most often has large gains. Most PDF documents are generated with object compression, but this does not seem to be the default for MiKTeX's `pdflatex`. For some PDF files (and especially package vignettes), using GhostScript can dramatically reduce the space taken by embedded images (often screenshots).

Where both GhostScript and `qpdf` are selected (when `gs_quality != "none"` and both executables are found), they are run in that order and the size reductions apply to the total compression achieved.

### Value

An object of class `c("compactPDF", "data.frame")`. This has two columns, the old and new sizes in bytes for the files that were changed.

There are `format` and `print` methods: the latter passes `...` to the `format` method, so will accept `ratio` and `diff` arguments.

### Note

The external tools used may change in future releases.

Versions of GhostScript 9.06 and later give several times better compression than 9.05 on some vignettes in CRAN packages.

**See Also**

[resaveRdaFiles](#).

Many other (and sometimes more effective) tools to compact PDF files are available, including Adobe Acrobat (not Reader). See the ‘Writing R Extensions’ manual.

---

delimMatch

*Delimited Pattern Matching*

---

**Description**

Match delimited substrings in a character vector, with proper nesting.

**Usage**

```
delimMatch(x, delim = c("{", "}"), syntax = "Rd")
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                         |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | a character vector.                                                                                                                                                                                                                                                                     |
| delim  | a character vector of length 2 giving the start and end delimiters. Future versions might allow for arbitrary regular expressions.                                                                                                                                                      |
| syntax | currently, always the string "Rd" indicating Rd syntax (i.e., ‘%’ starts a comment extending till the end of the line, and ‘\’ escapes). Future versions might know about other syntax, perhaps via ‘syntax tables’ allowing to flexibly specify comment, escape, and quote characters. |

**Value**

An integer vector of the same length as x giving the starting position (in characters) of the first match, or  $-1$  if there is none, with attribute "match.length" giving the length (in characters) of the matched text (or  $-1$  for no match).

**See Also**

[regexpr](#) for ‘simple’ pattern matching.

**Examples**

```
x <- c("\\value{foo}", "function(bar)")
delimMatch(x)
delimMatch(x, c("(", ")"))
```

---

|               |                                  |
|---------------|----------------------------------|
| dependsOnPkgs | <i>Find Reverse Dependencies</i> |
|---------------|----------------------------------|

---

## Description

Find ‘reverse’ dependencies of packages, that is those packages which depend on this one, and (optionally) so on recursively.

## Usage

```
dependsOnPkgs(pkgs,  
              dependencies = c("Depends", "Imports", "LinkingTo"),  
              recursive = TRUE, lib.loc = NULL,  
              installed =  
              utils::installed.packages(lib.loc, fields = "Enhances"))
```

## Arguments

|              |                                                                                                                                                                                                    |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgs         | a character vector of package names.                                                                                                                                                               |
| dependencies | a character vector listing the types of dependencies, a subset of <code>c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances")</code> . Character string "all" is shorthand for that vector. |
| recursive    | logical: should reverse dependencies of reverse dependencies (and so on) be included?                                                                                                              |
| lib.loc      | a character vector of R library trees, or NULL for all known trees (see <a href="#">.libPaths</a> ).                                                                                               |
| installed    | a result of calling <a href="#">installed.packages</a> .                                                                                                                                           |

## Value

A character vector of package names, which does not include any from pkgs.

## Examples

```
## there are few dependencies in a vanilla R installation:  
## lattice may not be installed  
dependsOnPkgs("lattice")
```

---

encoded\_text\_to\_latex *Translate non-ASCII Text to LaTeX Escapes*

---

## Description

Translate non-ASCII characters in text to LaTeX escape sequences.

## Usage

```
encoded_text_to_latex(x,
                      encoding = c("latin1", "latin2", "latin9",
                                   "UTF-8", "utf8"))
```

## Arguments

|          |                                                                                                                             |
|----------|-----------------------------------------------------------------------------------------------------------------------------|
| x        | a character vector.                                                                                                         |
| encoding | the encoding to be assumed. "latin9" is officially ISO-8859-15 or Latin-9, but known as latin9 to LaTeX's inputenc package. |

## Details

Non-ASCII characters in x are replaced by an appropriate LaTeX escape sequence, or '?' if there is no appropriate sequence.

Even if there is an appropriate sequence, it may not be supported by the font in use. Hyphen is mapped to '\-'.

## Value

A character vector of the same length as x.

## See Also

fileutils

*File Utilities*

---

## Description

Utilities for listing files, and manipulating file paths.

## Usage

```

file_ext(x)
file_path_as_absolute(x)
file_path_sans_ext(x, compression = FALSE)

list_files_with_exts(dir, exts, all.files = FALSE,
  full.names = TRUE)
list_files_with_type(dir, type, all.files = FALSE,
  full.names = TRUE, OS_subdirs = .OSType())

```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                  |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | character vector giving file paths.                                                                                                                                                                                                                                                                              |
| <code>compression</code> | logical: should compression extension <code>‘.gz’</code> , <code>‘.bz2’</code> or <code>‘.xz’</code> be removed first?                                                                                                                                                                                           |
| <code>dir</code>         | a character string with the path name to a directory.                                                                                                                                                                                                                                                            |
| <code>exts</code>        | a character vector of possible file extensions (excluding the leading dot).                                                                                                                                                                                                                                      |
| <code>all.files</code>   | a logical. If FALSE (default), only visible files are considered; if TRUE, all files are used.                                                                                                                                                                                                                   |
| <code>full.names</code>  | a logical indicating whether the full paths of the files found are returned (default), or just the file names.                                                                                                                                                                                                   |
| <code>type</code>        | a character string giving the ‘type’ of the files to be listed, as characterized by their extensions. Currently, possible values are <code>"code"</code> (R code), <code>"data"</code> (data sets), <code>"demo"</code> (demos), <code>"docs"</code> (R documentation), and <code>"vignette"</code> (vignettes). |
| <code>OS_subdirs</code>  | a character vector with the names of OS-specific subdirectories to possibly include in the listing of R code and documentation files. By default, the value of the environment variable <code>R_OSTYPE</code> , or if this is empty, the value of <code>.Platform\$OS.type</code> , is used.                     |

**Details**

`file_ext` returns the file (name) extensions (excluding the leading dot). (Only purely alphanumeric extensions are recognized.)

`file_path_as_absolute` turns a possibly relative file path absolute, performing tilde expansion if necessary. This is a wrapper for `normalizePath`. Currently, `x` must be a single existing path.

`file_path_sans_ext` returns the file paths without extensions (and the leading dot). (Only purely alphanumeric extensions are recognized.)

`list_files_with_exts` returns the paths or names of the files in directory `dir` with extension matching one of the elements of `exts`. Note that by default, full paths are returned, and that only visible files are used.

`list_files_with_type` returns the paths of the files in `dir` of the given ‘type’, as determined by the extensions recognized by R. When listing R code and documentation files, files in OS-specific subdirectories are included if present according to the value of `OS_subdirs`. Note that by default, full paths are returned, and that only visible files are used.

[file.path](#), [file.info](#), [list.files](#)

**Examples**

```
dir <- file.path(R.home(), "library", "stats")
list_files_with_exts(file.path(dir, "demo"), "R")
list_files_with_type(file.path(dir, "demo"), "demo") # the same
file_path_sans_ext(list.files(file.path(R.home("modules"))))
```

---

find\_gs\_cmd*Find a GhostScript Executable*

---

**Description**

Find a GhostScript executable in a cross-platform way.

**Usage**

```
find_gs_cmd(gs_cmd = "")
```

**Arguments**

gs\_cmd            The name, full or partial path of a GhostScript executable.

**Details**

The details differ by platform.

On a Unix-alike, the GhostScript executable is usually called gs. The name (and possibly path) of the command is taken first from argument gs\_cmd then from the environment variable R\_GSCMD and default gs. This is then looked for on the system path and the value returned if a match is found.

On Windows, the name of the command is taken from argument gs\_cmd then from the environment variables R\_GSCMD and GSC. If neither of those produces a suitable command name, gswin64c and gswin32c are tried in turn. In all cases the command is looked for on the system PATH.

Note that on Windows (and some other OSes) there are separate GhostScript executables to display Postscript/PDF files and to manipulate them: this function looks for the latter.

**Value**

A character string giving the full path to a GhostScript executable if one was found, otherwise an empty string.

**Examples**

```
## Not run:  
## Suppose a Solaris system has GhostScript 9.00 on the path and  
## 9.07 in /opt/csw/bin. Then one might set  
Sys.setenv(R_GSCMD = "/opt/csw/bin/gs")  
  
## End(Not run)
```

**Description**

Given a dependency matrix, will create a `DependsList` object for that package which will include the dependencies for that matrix, which ones are installed, which unresolved dependencies were found online, which unresolved dependencies were not found online, and any R dependencies.

**Usage**

```
getDepList(depMtrx, instPkgs, recursive = TRUE, local = TRUE,
           reduce = TRUE, lib.loc = NULL)

pkgDepends(pkg, recursive = TRUE, local = TRUE, reduce = TRUE,
           lib.loc = NULL)
```

**Arguments**

|                        |                                                                                                                                                         |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>depMtrx</code>   | A dependency matrix as from <code>package.dependencies</code>                                                                                           |
| <code>pkg</code>       | The name of the package                                                                                                                                 |
| <code>instPkgs</code>  | A matrix specifying all packages installed on the local system, as from <code>installed.packages</code>                                                 |
| <code>recursive</code> | Whether or not to include indirect dependencies                                                                                                         |
| <code>local</code>     | Whether or not to search only locally                                                                                                                   |
| <code>reduce</code>    | Whether or not to collapse all sets of dependencies to a minimal value                                                                                  |
| <code>lib.loc</code>   | What libraries to use when looking for installed packages. <code>NULL</code> indicates all library directories in the user's <code>.libPaths()</code> . |

**Details**

The function `pkgDepends` is a convenience function which wraps `getDepList` and takes as input a package name. It will then query `installed.packages` and also generate a dependency matrix, calling `getDepList` with this information and returning the result.

These functions will retrieve information about the dependencies of the matrix, resulting in a `DependsList` object. This is a list with four elements:

**Depends** A vector of the dependencies for this package.

**Installed** A vector of the dependencies which have been satisfied by the currently installed packages.

**Found** A list representing the dependencies which are not in `Installed` but were found online. This list has element names which are the URLs for the repositories in which packages were found and the elements themselves are vectors of package names which were found in the respective repositories. If `local = TRUE`, the `Found` element will always be empty.

**R** Any R version dependencies.

If recursive is TRUE, any package that is specified as a dependency will in turn have its dependencies included (and so on), these are known as indirect dependencies. If recursive is FALSE, only the dependencies directly stated by the package will be used.

If local is TRUE, the system will only look at the user's local install and not online to find unresolved dependencies.

If reduce is TRUE, the system will collapse the fields in the DependsList object such that a minimal set of dependencies are specified (for instance if there was 'foo, foo (>= 1.0.0), foo (>= 1.3.0)', it would only return 'foo (>= 1.3.0)').

### Value

An object of class "DependsList".

### Author(s)

Jeff Gentry

### See Also

[installFoundDepends](#)

### Examples

```
pkgDepends("tools", local = FALSE)
```

---

getVignetteInfo

*Get information on installed vignettes.*

---

### Description

This function gets information on installed vignettes.

### Usage

```
getVignetteInfo(package = NULL, lib.loc = NULL, all = TRUE)
```

### Arguments

|         |                                                                      |
|---------|----------------------------------------------------------------------|
| package | Which package to look in, or NULL for all packages.                  |
| lib.loc | Which library to look in.                                            |
| all     | Whether to search all installed packages, or just attached packages. |

**Value**

A matrix with columns

|         |                                                 |
|---------|-------------------------------------------------|
| Package | the name of the package                         |
| Dir     | the directory where the package is installed    |
| Topic   | the name of the vignette                        |
| File    | the base filename of the source of the vignette |
| Title   | the title of the vignette                       |
| R       | the tangled R source from the vignette          |
| PDF     | the PDF or HTML file for display                |

**Note**

The last column of the result is named PDF for historical reasons, but it may contain a filename of a PDF or HTML document.

**See Also**

[pkgVignettes](#) is a similar function that can work on an uninstalled package.

**Examples**

```
getVignetteInfo("grid")
```

---

HTMLheader

*Generate a standard HTML header for R help*

---

**Description**

This function generates the standard HTML header used on R help pages.

**Usage**

```
HTMLheader(title = "R", logo = TRUE, up = NULL,  
            top = file.path(Rhome, "doc/html/index.html"),  
            Rhome = "",  
            css = file.path(Rhome, "doc/html/R.css"),  
            headerTitle = paste("R:", title),  
            outputEncoding = "UTF-8")
```

Arguments

|                |                                                                                                   |
|----------------|---------------------------------------------------------------------------------------------------|
| title          | The title to display and use in the HTML headers. Should have had any HTML escaping already done. |
| logo           | Whether to display the R logo after the title.                                                    |
| up             | Which page (if any) to link to on the “up” button.                                                |
| top            | Which page (if any) to link to on the “top” button.                                               |
| Rhome          | A <b>relative</b> path to the R home directory. See the ‘Details’.                                |
| css            | The relative URL for the Cascading Style Sheet.                                                   |
| headerTitle    | The title used in the headers.                                                                    |
| outputEncoding | The declared encoding for the whole page.                                                         |

Details

The up and top links should be relative to the current page. The Rhome path default works with dynamic help; for static help, a relative path (e.g., ‘. / . .’) to it should be used.

Value

A character vector containing the lines of an HTML header which can be used to start a page in the R help system.

Examples

```
cat(HTMLheader("This is a sample header"), sep="\n")
```

---

|           |                                                      |
|-----------|------------------------------------------------------|
| HTMLlinks | <i>Collect HTML Links from Package Documentation</i> |
|-----------|------------------------------------------------------|

---

Description

Compute relative file paths for URLs to other package’s installed HTML documentation.

Usage

```
findHTMLlinks(pkgDir = "", lib.loc = NULL, level = 0:2)
```

Arguments

|         |                                                                                                                       |
|---------|-----------------------------------------------------------------------------------------------------------------------|
| pkgDir  | the top-level directory of an installed package. The default indicates no package.                                    |
| lib.loc | character vector describing the location of R library trees to scan: the default indicates <code>.libPaths()</code> . |
| level   | Which level(s) to include.                                                                                            |

**Details**

findHTMLlinks tries to resolve links from one help page to another. It uses in decreasing priority

- The package in pkgDir: this is used when converting HTML help for that package (level 0).
- The base and recommended packages (level 1).
- Other packages found in the library trees specified by lib.loc in the order of the trees and alphabetically within a library tree (level 2).

**Value**

A named character vector of file paths, relative to the 'html' directory of an installed package. So these are of the form `"../..../somepkg/html/sometopic.html"`.

**Author(s)**

Duncan Murdoch, Brian Ripley

---

|                     |                                                      |
|---------------------|------------------------------------------------------|
| installFoundDepends | <i>A function to install unresolved dependencies</i> |
|---------------------|------------------------------------------------------|

---

**Description**

This function will take the Found element of a pkgDependsList object and attempt to install all of the listed packages from the specified repositories.

**Usage**

```
installFoundDepends(depPkgList, ...)
```

**Arguments**

|            |                                                          |
|------------|----------------------------------------------------------|
| depPkgList | A Found element from a pkgDependsList object             |
| ...        | Arguments to pass on to <a href="#">install.packages</a> |

**Details**

This function takes as input the Found list from a pkgDependsList object. This list will have element names being URLs corresponding to repositories and the elements will be vectors of package names. For each element, [install.packages](#) is called for that URL to install all packages listed in the vector.

**Author(s)**

Jeff Gentry

**See Also**

[pkgDepends](#), [install.packages](#)

## Examples

```
## Set up a temporary directory to install packages to
tmp <- tempfile()
dir.create(tmp)

pDL <- pkgDepends("tools", local = FALSE)
installFoundDepends(pDL$Found, destdir = tmp)
```

---

loadRdMacros

*Load user-defined Rd help system macros.*

---

## Description

Loads macros from an ‘.Rd’ file, or from several ‘.Rd’ files contained in a package.

## Usage

```
loadRdMacros(file, macros = TRUE)
loadPkgRdMacros(pkgdir, macros)
```

## Arguments

|        |                                                                                                                      |
|--------|----------------------------------------------------------------------------------------------------------------------|
| file   | A file in Rd format containing macro definitions.                                                                    |
| macros | TRUE or a previous set of macro definitions, in the format expected by the <a href="#">parse_Rd</a> macros argument. |
| pkgdir | The base directory of a source package or an installed package.                                                      |

## Details

The files parsed by this function should contain only macro definitions; a warning will be issued if anything else other than comments or white space is found.

The macros argument may be a filename of a base set of macros, or the result of a previous call to `loadRdMacros` or `loadPkgRdMacros` in the same session. These results should be assumed to be valid only within the current session.

The `loadPkgMacros` function first looks for an “RdMacros” entry in the package ‘DESCRIPTION’ file. If present, it should contain a comma-separated list of other package names; their macros will be loaded before those of the current package. It will then look in the current package for ‘.Rd’ files in the ‘man/macros’ or ‘help/macros’ subdirectories, and load those.

## Value

These functions each return an environment containing objects with the names of the newly defined macros from the last file processed. The parent environment will be macros from the previous file, and so on. The first file processed will have `emptyenv()` as its parent.

**Author(s)**

Duncan Murdoch

See the ‘Writing R Extensions’ manual for the syntax of Rd files, or <http://developer.r-project.org/parseRd.pdf> for a technical discussion.

**See Also**

[parse\\_Rd](#)

**Examples**

```
f <- tempfile()
writeLines(paste0("\\newcommand{\\logo}{\\if{html}{\\figure{logo.jpg}},
                  \"\\if{latex}{\\figure{logo.jpg}{options: width=0.5in}}}\"),
          f)
m <- loadRdMacros(f)
ls(m)
ls(parent.env(m))
ls(parent.env(parent.env(m)))
```

---

make\_translations\_pkg *Package the Current Translations in the R sources*

---

**Description**

A utility for R Core members to prepare a package of updated translations.

**Usage**

```
make_translations_pkg(srcdir, outDir = ".", append = "-1")
```

**Arguments**

|        |                                                                                         |
|--------|-----------------------------------------------------------------------------------------|
| srcdir | The R source directory.                                                                 |
| outDir | The directory into which to place the prepared package.                                 |
| append | The suffix for the package version number, e.g. 3.0.0-1 will be the default in R 3.0.0. |

**Details**

This extracts the translations in a current R source distribution and packages them as a source package called **translations** which can be distributed on CRAN and installed by [update.packages](#). This allows e.g. the translations shipped in R 3.x.y to be updated to those currently in ‘R-patched’, even by a user without administrative privileges.

The package has a ‘Depends’ field which restricts it to versions 3.x.\* for a single x.

md5sum

*Compute MD5 Checksums***Description**

Compute the 32-byte MD5 hashes of one or more files.

**Usage**

```
md5sum(files)
```

**Arguments**

`files`                      character. The paths of file(s) whose contents are to be hashed.

**Details**

A MD5 ‘hash’ or ‘checksum’ or ‘message digest’ is a 128-bit summary of the file contents represented by 32 hexadecimal digits. Files with different MD5 sums are different: only very exceptionally (and usually with the intent to deceive) are those with the same sums different.

On Windows all files are read in binary mode (as the md5sum utilities there do): on other OSes the files are read in the default mode (almost always text mode where there is more than one).

MD5 sums are used as a check that R packages have been unpacked correctly and not subsequently modified.

**Value**

A character vector of the same length as `files`, with names equal to `files`. The elements will be NA for non-existent or unreadable files, otherwise a 32-character string of hexadecimal digits.

**Source**

The underlying C code was written by Ulrich Drepper and extracted from a 2001 release of glibc.

**See Also**

[checkMD5sums](#)

**Examples**

```
as.vector(md5sum(dir(R.home(), pattern = "^COPY", full.names = TRUE)))
```

---

package.dependencies    *Check Package Dependencies*

---

### Description

Parses and checks the dependencies of a package against the currently installed version of R (and other packages).

### Usage

```
package.dependencies(x, check = FALSE,
                    depLevel =
                      c("Depends", "Imports", "Suggests"))
```

### Arguments

|          |                                                                                                |
|----------|------------------------------------------------------------------------------------------------|
| x        | A matrix of package descriptions as returned by <a href="#">available.packages</a> .           |
| check    | If TRUE, return logical vector of check results. If FALSE, return parsed list of dependencies. |
| depLevel | Whether to look for Depends or Suggests level dependencies. Can be abbreviated.                |

### Details

Currently we only check if the package conforms with the currently running version of R. In the future we might add checks for inter-package dependencies.

### See Also

[update.packages](#)

---

package\_dependencies    *Computations on the Dependency Hierarchy of Packages*

---

### Description

Find (recursively) dependencies or reverse dependencies of packages.

### Usage

```
package_dependencies(packages = NULL, db,
                    which = c("Depends", "Imports", "LinkingTo"),
                    recursive = FALSE, reverse = FALSE, verbose = getOption("verbose"))
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| packages  | a character vector of package names.                                                                                                                                                                                                                                                    |
| db        | character matrix as from <a href="#">available.packages()</a> , or data frame variants thereof. Alternatively, a package database like the one available from <a href="https://cran.r-project.org/web/packages/packages.rds">https://cran.r-project.org/web/packages/packages.rds</a> . |
| which     | a character vector listing the types of dependencies, a subset of <code>c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances")</code> . Character string "all" is shorthand for that vector, character string "most" for the same vector without "Enhances".                      |
| recursive | logical: should (reverse) dependencies of (reverse) dependencies (and so on) be included?                                                                                                                                                                                               |
| reverse   | logical: if FALSE (default), regular dependencies are calculated, otherwise reverse dependencies.                                                                                                                                                                                       |
| verbose   | logical indicating if output should monitor the package search cycles.                                                                                                                                                                                                                  |

**Value**

Named list with one element for each package in argument `packages`, each consists of a character vector naming the (recursive) (reverse) dependencies of that package.

For given packages which are not found in the db, NULL entries are returned, as opposed to `character(0)` entries which indicate no dependencies.

**See Also**

[dependsOnPkgs](#), and [package.dependencies](#) for checking dependencies.

**Examples**

```
## Not run:
pdb <- available.packages()
deps <- package_dependencies(packages = "MASS", pdb,
                             which = c("Depends", "Imports", "LinkingTo", "Suggests"),
                             recursive = TRUE, reverse = TRUE)

## End(Not run)
```

---

parseLatex

*These experimental functions work with a subset of LaTeX code.*

---

**Description**

The `parseLatex` function parses LaTeX source, producing a structured object; `deparseLatex` reverses the process. The `latexToUtf8` function takes a LaTeX object, and processes a number of different macros to convert them into the corresponding UTF-8 characters.

**Usage**

```

parseLatex(text, filename = deparse(substitute(text)),
           verbose = FALSE,
           verbatim = c("verbatim", "verbatim*",
                        "Sinput", "Soutput"))
deparseLatex(x, dropBraces = FALSE)
latexToUtf8(x)

```

**Arguments**

|            |                                                                                      |
|------------|--------------------------------------------------------------------------------------|
| text       | A character vector containing LaTeX source code.                                     |
| filename   | A filename to use in syntax error messages.                                          |
| verbose    | If TRUE, print debug error messages.                                                 |
| verbatim   | A character vector containing the names of LaTeX environments holding verbatim text. |
| x          | A "LaTeX" object.                                                                    |
| dropBraces | Drop unnecessary braces when displaying a "LaTeX" object.                            |

**Details**

The parser does not recognize all legal LaTeX code, only relatively simple examples. It does not associate arguments with macros, that needs to be done after parsing, with knowledge of the definitions of each macro. The main intention for this function is to process simple LaTeX code used in bibliographic references, not fully general LaTeX documents.

Verbose text is allowed in two forms: the `\verb` macro (with single character delimiters), and environments whose names are listed in the `verbatim` argument.

**Value**

The `parseLatex()` function returns a recursive object of class "LaTeX". Each of the entries in this object will have a `"latex_tag"` attribute identifying its syntactic role.

The `deparseLatex()` function returns a single element character vector, possibly containing embedded newlines.

The `latexToUtf8()` function returns a modified version of the "LaTeX" object that was passed to it.

**Author(s)**

Duncan Murdoch

**Examples**

```

latex <- parseLatex("fa\\c{c}ile")
deparseLatex(latexToUtf8(latex))

```

---

 parse\_Rd

---

*Parse an Rd file*

---

## Description

This function reads an R documentation (Rd) file and parses it, for processing by other functions.

## Usage

```
parse_Rd(file, srcfile = NULL, encoding = "unknown",
         verbose = FALSE, fragment = FALSE, warningCalls = TRUE,
         macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"),
         permissive = FALSE)
## S3 method for class 'Rd'
print(x, deparse = FALSE, ...)
## S3 method for class 'Rd'
as.character(x, deparse = FALSE, ...)
```

## Arguments

|              |                                                                                                                     |
|--------------|---------------------------------------------------------------------------------------------------------------------|
| file         | A filename or text-mode connection. At present filenames work best.                                                 |
| srcfile      | NULL, or a "srcfile" object. See the 'Details' section.                                                             |
| encoding     | Encoding to be assumed for input strings.                                                                           |
| verbose      | Logical indicating whether detailed parsing information should be printed.                                          |
| fragment     | Logical indicating whether file represents a complete Rd file, or a fragment.                                       |
| warningCalls | Logical: should parser warnings include the call?                                                                   |
| macros       | Filename or environment from which to load additional macros, or a logical value. See the Details below.            |
| permissive   | Logical indicating that unrecognized macros should be treated as text with no warning.                              |
| x            | An object of class Rd.                                                                                              |
| deparse      | If TRUE, attempt to reinstate the escape characters so that the resulting characters will parse to the same object. |
| ...          | Further arguments to be passed to or from other methods.                                                            |

## Details

This function parses 'Rd' files according to the specification given in <http://developer.r-project.org/parseRd.pdf>.

It generates a warning for each parse error and attempts to continue parsing. In order to continue, it is generally necessary to drop some parts of the file, so such warnings should not be ignored.

Files without a marked encoding are by default assumed to be in the native encoding. An alternate default can be set using the encoding argument. All text in files is translated to the UTF-8 encoding in the parsed object.

As from R version 3.2.0, User-defined macros may be given in a separate file using ‘\newcommand’ or ‘\renewcommand’. An environment may also be given: it would be produced by `loadRdMacros`, `loadPkgRdMacros`, or by a previous call to `parse_Rd`. If a logical value is given, only the default built-in macros will be used; FALSE indicates that no “macros” attribute will be returned with the result.

The permissive argument allows text to be parsed that is not completely in Rd format. Typically it would be LaTeX code, used in an Rd fragment, e.g. in a `bibentry`. With `permissive = TRUE`, this will be passed through as plain text. Since `parse_Rd` doesn’t know how many arguments belong in LaTeX macros, it will guess based on the presence of braces after the macro; this is not infallible.

### Value

`parse_Rd` returns an object of class “Rd”. The internal format of this object is subject to change. The `as.character()` and `print()` methods defined for the class return character vectors and print them, respectively.

Unless `macros = FALSE`, the object will have an attribute named “macros”, which is an environment containing the macros defined in file, in a format that can be used for further `parse_Rd` calls in the same session. It is not guaranteed to work if saved to a file and reloaded in a different session.

---

pskill

*Kill a Process*

---

### Description

`pskill` sends a signal to a process, usually to terminate it.

### Usage

```
pskill(pid, signal = SIGTERM)
```

```
SIGHUP  
SIGINT  
SIGQUIT  
SIGKILL  
SIGTERM
```

SIGSTOP  
SIGTSTP  
SIGCHLD  
SIGUSR1  
SIGUSR2

### Arguments

|        |                                                                                        |
|--------|----------------------------------------------------------------------------------------|
| pid    | positive integers: one or more process IDs as returned by <a href="#">Sys.getpid</a> . |
| signal | integer, most often one of the symbolic constants.                                     |

### Details

Signals are a C99 concept, but only a small number are required to be supported (of those listed, only SIGINT and SIGTERM). They are much more widely used on POSIX operating systems (which should define all of those listed here), which also support a `kill` system call to send a signal to a process, most often to terminate it. Function `pskill` provides a wrapper: it silently ignores invalid values of its arguments, including zero or negative pids.

In normal use on a Unix-alike, `Ctrl-C` sends SIGINT, `Ctrl-\` sends SIGQUIT and `Ctrl-Z` sends SIGTSTP: that and SIGSTOP suspend a process which can be resumed by SIGCONT.

The signals are small integers, but the actual numeric values are not standardized (and most do differ between OSes). The `SIG*` objects contain the appropriate integer values for the current platform (or `NA_INTEGER_` if the signal is not defined).

Only SIGINT and SIGKILL will be defined on Windows, and `pskill` will always use the Windows system call `TerminateProcess`.

### Value

A logical vector of the same length as `pid`, `TRUE` (for success) or `FALSE`, invisibly.

### See Also

Package **parallel** has several means to launch child processes which record the process IDs.

[psnice](#)

### Examples

```
## Not run:  
pskill(c(237, 245), SIGKILL)  
  
## End(Not run)
```

---

psnice

---

*Get or Set the Priority (Niceness) of a Process*

---

## Description

Get or set the ‘niceness’ of the current process, or one or more other processes.

## Usage

```
psnice(pid = Sys.getpid(), value = NA_integer_)
```

## Arguments

|       |                                                                                                 |
|-------|-------------------------------------------------------------------------------------------------|
| pid   | positive integers: the process IDs of one or more processes: defaults to the R session process. |
| value | The niceness to be set, or NA for an enquiry.                                                   |

## Details

POSIX operating systems have a concept of process priorities, usually from 0 to 39 (or 40) with 20 being a normal priority and (somewhat confusingly) larger numeric values denoting lower priority. To add to the confusion, there is a ‘niceness’ value, the amount by which the priority numerically exceeds 20 (which can be negative). Processes with high niceness will receive less CPU time than those with normal priority. On some OSes, processes with niceness +19 are only run when the system would otherwise be idle.

On many OSes utilities such as `top` report the priority and not the niceness. Niceness is used by the utility ‘/usr/bin/renice’: ‘/usr/bin/nice’ (and `/usr/bin/renice -n`) specifies an *increment* in niceness.

Only privileged users (usually super-users) can lower the niceness.

Windows has a slightly different concept of ‘priority classes’. We have mapped the idle priority to niceness 19, ‘below normal’ to 15, normal to 0, ‘above normal’ to -5 and ‘realtime’ to -10. Unlike Unix-alikes, a non-privileged user can increase the priority class on Windows (but using ‘realtime’ is inadvisable).

## Value

An integer vector of *previous* niceness values, NA if unknown for any reason.

## See Also

Various functions in package **parallel** create child processes whose priority may need to be changed. [pskill](#).

**Description**

Functions for performing various quality checks.

**Usage**

```
checkDocFiles(package, dir, lib.loc = NULL)
checkDocStyle(package, dir, lib.loc = NULL)
checkReplaceFuns(package, dir, lib.loc = NULL)
checkS3methods(package, dir, lib.loc = NULL)
```

**Arguments**

|                      |                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code> | a character string naming an installed package.                                                                                                                                                                                             |
| <code>dir</code>     | a character string specifying the path to a package's root source directory. This should contain the subdirectories 'R' (for R code) and 'man' with R documentation sources (in Rd format). Only used if <code>package</code> is not given. |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                                          |

**Details**

`checkDocFiles` checks, for all Rd files in a package, whether all arguments shown in the usage sections of the Rd file are documented in its arguments section. It also reports duplicated entries in the arguments section, and 'over-documented' arguments which are given in the arguments section but not in the usage. Note that the match is for the usage section and not a possibly existing synopsis section, as the usage is what gets displayed.

`checkDocStyle` investigates how (S3) methods are shown in the usages of the Rd files in a package. It reports the methods shown by their full name rather than using the Rd `\method` markup for indicating S3 methods. Earlier versions of R also reported about methods shown along with their generic, which typically caused problems for the documentation of the primary argument in the generic and its methods. With `\method` now being expanded in a way that class information is preserved, joint documentation is no longer necessarily a problem. (The corresponding information is still contained in the object returned by `checkDocStyle`.)

`checkReplaceFuns` checks whether replacement functions or S3/S4 replacement methods in the package R code have their final argument named `value`.

`checkS3methods` checks whether all S3 methods defined in the package R code have all arguments of the corresponding generic, with positional arguments of the generics in the same positions for the method. As an exception, the first argument of a formula method *may* be called `formula` even if this is not the name used by the generic. The rules when `...` is involved are subtle: see the source code. Functions recognized as S3 generics are those with a call to `UseMethod` in their body, internal S3 generics (see [InternalMethods](#)), and S3 group generics (see [Math](#)). Possible

dispatch under a different name is not taken into account. The generics are sought first in the given package, then in the **base** package and (currently) the packages **graphics**, **stats**, and **utils** added in R 1.9.0 by splitting the former **base**, and, if an installed package is tested, also in the loaded namespaces/packages listed in the package's 'DESCRIPTION' Depends field.

If using an installed package, the checks needing access to all R objects of the package will load the package (unless it is the **base** package), after possibly detaching an already loaded version of the package.

## Value

The functions return objects of class the same as the respective function names containing the information about problems detected. There are print methods for nicely displaying the information contained in such objects.

---

Rd2HTML

*Rd Converters*

---

## Description

These functions take the output of the [parse\\_Rd](#) function and produce a help page from it. As they are mainly intended for internal use, their interfaces are subject to change.

## Usage

```
Rd2HTML(Rd, out = "", package = "", defines = .Platform$OS.type,
        Links = NULL, Links2 = NULL,
        stages = "render", outputEncoding = "UTF-8",
        dynamic = FALSE, no_links = FALSE, fragment = FALSE,
        stylesheet = "R.css", ...)
```

```
Rd2txt(Rd, out = "", package = "", defines = .Platform$OS.type,
        stages = "render", outputEncoding = "",
        fragment = FALSE, options, ...)
```

```
Rd2latex(Rd, out = "", defines = .Platform$OS.type,
        stages = "render", outputEncoding = "ASCII",
        fragment = FALSE, ..., writeEncoding = TRUE)
```

```
Rd2ex(Rd, out = "", defines = .Platform$OS.type,
        stages = "render", outputEncoding = "UTF-8",
        commentDontrun = TRUE, commentDonttest = FALSE, ...)
```

## Arguments

|                      |                                                               |
|----------------------|---------------------------------------------------------------|
| <code>Rd</code>      | a filename or Rd object to use as input.                      |
| <code>out</code>     | a filename or connection object to which to write the output. |
| <code>package</code> | the package to list in the output.                            |

|                              |                                                                                                                      |
|------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>defines</code>         | string(s) to use in <code>#ifdef</code> tests.                                                                       |
| <code>stages</code>          | at which stage ("build", "install", or "render") should <code>\Sexpr</code> macros be executed? See the notes below. |
| <code>outputEncoding</code>  | see the 'Encodings' section below.                                                                                   |
| <code>dynamic</code>         | logical: set links for render-time resolution by dynamic help system.                                                |
| <code>no_links</code>        | logical: suppress hyperlinks to other help topics. Used by R CMD <code>Rdconv</code> .                               |
| <code>fragment</code>        | logical: should fragments of Rd files be accepted? See the notes below.                                              |
| <code>stylesheet</code>      | character: a URL for a stylesheet to be used in the header of the HTML output page.                                  |
| <code>Links, Links2</code>   | NULL or a named (by topics) character vector of links, as returned by <code>findHTMLlinks</code> .                   |
| <code>options</code>         | An optional named list of options to pass to <code>Rd2txt_options</code> .                                           |
| <code>...</code>             | additional parameters to pass to <code>parse_Rd</code> when Rd is a filename.                                        |
| <code>writeEncoding</code>   | should <code>\inputencoding</code> lines be written in the file for non-ASCII encodings?                             |
| <code>commentDontrun</code>  | should <code>\dontrun</code> sections be commented out?                                                              |
| <code>commentDonttest</code> | should <code>\donttest</code> sections be commented out?                                                             |

## Details

These functions convert help documents: `Rd2HTML` produces HTML, `Rd2txt` produces plain text, `Rd2latex` produces LaTeX. `Rd2ex` extracts the examples in the format used by `example` and `R` utilities.

Each of the functions accepts a filename for an Rd file, and will use `parse_Rd` to parse it before applying the conversions or checks.

The difference between arguments `Link` and `Link2` is that links are looked in them in turn, so lazy-evaluation can be used to only do a second-level search for links if required.

Note that the default for `Rd2latex` is to output ASCII, including using the second option of `\enc` markup. This was chosen because use of UTF-8 in LaTeX requires version '2005/12/01' or later, and even with that version the coverage of UTF-8 glyphs is not extensive (and not even as complete as Latin-1).

`Rd2txt` will format text paragraphs to a width determined by width, with appropriate margins. The default is to be close to the rendering in versions of R < 2.10.0.

`Rd2txt` will use directional quotes (see `sQuote`) if option "useFancyQuotes" is true (the default) and the current encoding is UTF-8.

Various aspects of formatting by `Rd2txt` are controlled by the `options` argument, documented with the `Rd2txt_options` function. Changes made using options are temporary, those made with `Rd2txt_options` are persistent.

When `fragment = TRUE`, the Rd file will be rendered with no processing of `\Sexpr` elements or conditional defines using `#ifdef` or `#ifndef`. Normally a fragment represents text within a section, but if the first element of the fragment is a section macro, the whole fragment will be rendered as a series of sections, without the usual sorting.

### Value

These functions are executed mainly for the side effect of writing the converted help page. Their value is the name of the output file (invisibly). For `Rd2latex`, the output name is given an attribute `"latexEncoding"` giving the encoding of the file in a form suitable for use with the LaTeX `'inputenc'` package.

### Encodings

Rd files are normally intended to be rendered on a wide variety of systems, so care must be taken in the encoding of non-ASCII characters. In general, any such encoding should be declared using the `'encoding'` section for there to be any hope of correct rendering.

For output, the `outputEncoding` argument will be used: `outputEncoding = ""` will choose the native encoding for the current system.

If the text cannot be converted to the `outputEncoding`, byte substitution will be used (see [iconv](#)): `Rd2latex` and `Rd2ex` give a warning.

### Note

The `\Sexpr` macro is a new addition to Rd files. It includes R code that will be executed at one of three times: *build* time (when a package's source code is built into a tarball), *install* time (when the package is installed or built into a binary package), and *render* time (when the man page is converted to a readable format).

For example, this man page was:

1. built on 2015-12-10 at 13:09:57,
2. installed on 2015-12-10 at 13:09:57, and
3. rendered on 2015-12-10 at 13:12:30.

Rd2txt\_options

*Set formatting options for text help*

---

## Description

This function sets various options for displaying text help.

## Usage

```
Rd2txt_options(...)
```

## Arguments

...                    A list containing named options, or options passed as individual named arguments. See below for currently defined ones.

## Details

This function persistently sets various formatting options for the `Rd2txt` function which is used in displaying text format help. Currently defined options are:

**width** (default 80): The width of the output page.

**minIndent** (default 10): The minimum indent to use in a list.

**extraIndent** (default 4): The extra indent to use in each level of nested lists.

**sectionIndent** (default 5): The indent level for a section.

**sectionExtra** (default 2): The extra indentation for each nested section level.

**itemBullet** (default "`*`", with the asterisk replaced by a Unicode bullet in UTF-8 and most Windows locales): The symbol to use as a bullet in itemized lists.

**enumFormat** : A function to format item numbers in enumerated lists.

**showURLs** (default FALSE): Whether to show URLs when expanding `\href` tags.

**code\_quote** (default TRUE): Whether to render `\code` and similar with single quotes.

**underline\_titles** (default TRUE): Whether to render section titles with underlines (via backspacing).

**Value**

If called with no arguments, returns all option settings in a list. Otherwise, it changes the named settings and invisibly returns their previous values.

**Author(s)**

Duncan Murdoch

**See Also**

[Rd2txt](#)

**Examples**

```
# The itemBullet is locale-specific
saveOpts <- Rd2txt_options()
saveOpts
Rd2txt_options(minIndent = 4)
Rd2txt_options()
Rd2txt_options(saveOpts)
Rd2txt_options()
```

---

|       |                                  |
|-------|----------------------------------|
| Rdiff | <i>Difference R Output Files</i> |
|-------|----------------------------------|

---

**Description**

Given two R output files, compute differences ignoring headers, footers and some other differences.

**Usage**

```
Rdiff(from, to, useDiff = FALSE, forEx = FALSE,
      nullPointers = TRUE, Log = FALSE)
```

**Arguments**

|              |                                                                                             |
|--------------|---------------------------------------------------------------------------------------------|
| from, to     | filepaths to be compared                                                                    |
| useDiff      | should diff always be used to compare results?                                              |
| forEx        | logical: extra pruning for ‘-Ex.Rout’ files to exclude the header.                          |
| nullPointers | logical: should the displayed addresses of pointers be set to 0x00000000 before comparison? |
| Log          | logical: should the returned value include a log of differences found?                      |

### Details

The R startup banner and any timing information from R CMD BATCH are removed from both files, together with lines about loading packages. UTF-8 fancy quotes (see [sQuote](#)) and on Windows, Windows' so-called 'smart quotes', are mapped to a simple quote. Addresses of environments, compiled bytecode and other exotic types expressed as hex addresses (e.g., <environment: 0x12345678>) are mapped to 0x00000000. The files are then compared line-by-line. If there are the same number of lines and useDiff is false, a simple diff -b -like display of differences is printed (which ignores trailing spaces and differences in numbers of consecutive spaces), otherwise diff -bw is called on the edited files. (This tries to ignore all differences in whitespace: note that flag '-w' is not required by POSIX but is supported by GNU, Solaris and FreeBSD versions.)

This can compare uncompressed PDF files, ignoring differences in creation and modification dates.

### Value

If Log is true, a list with components status (see below) and out, a character vector of descriptions of differences, possibly of zero length.

Otherwise, a status indicator, 0L if and only if no differences were found.

### See Also

The shell script run as R CMD Rdiff.

---

Rdindex

*Generate Index from Rd Files*

---

### Description

Print a 2-column index table with names and titles from given R documentation files to a given output file or connection. The titles are nicely formatted between two column positions (typically 25 and 72, respectively).

### Usage

```
Rdindex(RdFiles, outFile = "", type = NULL,
        width = 0.9 * getOption("width"), indent = NULL)
```

### Arguments

|         |                                                                                                                                                                                                                                                                                  |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RdFiles | a character vector specifying the Rd files to be used for creating the index, either by giving the paths to the files, or the path to a single directory with the sources of a package.                                                                                          |
| outFile | a connection, or a character string naming the output file to print to. "" (the default) indicates output to the console.                                                                                                                                                        |
| type    | a character string giving the documentation type of the Rd files to be included in the index, or NULL (the default). The type of an Rd file is typically specified via the \docType tag; if type is "data", Rd files whose <i>only</i> keyword is datasets are included as well. |

|        |                                                                                                                                |
|--------|--------------------------------------------------------------------------------------------------------------------------------|
| width  | a positive integer giving the target column for wrapping lines in the output.                                                  |
| indent | a positive integer specifying the indentation of the second column. Must not be greater than width/2, and defaults to width/3. |

### Details

If a name is not a valid alias, the first alias (or the empty string if there is none) is used instead.

---

|              |                                   |
|--------------|-----------------------------------|
| RdTextFilter | <i>Select text in an Rd file.</i> |
|--------------|-----------------------------------|

---

### Description

This function blanks out all non-text in an Rd file, for spell checking or other uses.

### Usage

```
RdTextFilter(ifile, encoding = "unknown", keepSpacing = TRUE,
             drop = character(), keep = character(),
             macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"))
```

### Arguments

|             |                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------|
| ifile       | An input file specified as a filename or connection, or an "Rd" object from <a href="#">parse_Rd</a> . |
| encoding    | An encoding name to pass to <a href="#">parse_Rd</a> .                                                 |
| keepSpacing | Whether to try to leave the text in the same lines and columns as in the original file.                |
| drop        | Additional sections of the Rd to drop.                                                                 |
| keep        | Sections of the Rd file to keep.                                                                       |
| macros      | Macro definitions to assume when parsing. See <a href="#">parse_Rd</a> .                               |

### Details

This function parses the Rd file, then walks through it, element by element. Items with tag "TEXT" are kept in the same position as they appeared in the original file, while other parts of the file are replaced with blanks, so a spell checker such as [aspell](#) can check only the text and report the position in the original file. (If keepSpacing is FALSE, blank filling will not occur, and text will not be output in its original location.)

By default, the tags \S3method, \S4method, \command, \docType, \email, \encoding, \file, \keyword, \link, \linkS4class, \method, \pkg, and \var are skipped. Additional tags can be skipped by listing them in the drop argument; listing tags in the keep argument will stop them from being skipped. It is also possible to keep any of the c("RCODE", "COMMENT", "VERB") tags, which correspond to R-like code, comments, and verbatim text respectively, or to drop "TEXT".

**Value**

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Rd file.

**Note**

The filter attempts to merge text elements into single words when markup in the Rd file is used to highlight just the start of a word.

**Author(s)**

Duncan Murdoch

**See Also**

[aspell](#), for which this is an acceptable filter.

---

Rdutils

*Rd Utilities*

---

**Description**

Utilities for computing on the information in Rd objects.

**Usage**

```
Rd_db(package, dir, lib.loc = NULL)
```

**Arguments**

|                      |                                                                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code> | a character string naming an installed package.                                                                                                                                                                      |
| <code>dir</code>     | a character string specifying the path to a package's root source directory. This should contain the subdirectory 'man' with R documentation sources (in Rd format). Only used if <code>package</code> is not given. |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                   |

**Details**

`Rd_db` builds a simple database of all Rd objects in a package, as a list of the results of running [parse\\_Rd](#) on the Rd source files in the package and processing platform conditionals.

**See Also**

[parse\\_Rd](#)

## Examples

```
## Build the Rd db for the (installed) base package.
db <- Rd_db("base")

## Keyword metadata per Rd object.
keywords <- lapply(db, tools:::Rd_get_metadata, "keyword")
## Tabulate the keyword entries.
kw_table <- sort(table(unlist(keywords)))
## The 5 most frequent ones:
rev(kw_table)[1 : 5]
## The "most informative" ones:
kw_table[kw_table == 1]
```

```
## Concept metadata per Rd file.
concepts <- lapply(db, tools:::Rd_get_metadata, "concept")
## How many files already have \concept metadata?
sum(sapply(concepts, length) > 0)
## How many concept entries altogether?
length(unlist(concepts))
```

---

read.00Index

*Read 00Index-style Files*

---

## Description

Read item/description information from ‘00Index’-like files. Such files are description lists rendered in tabular form, and currently used for the ‘INDEX’ and ‘demo/00Index’ files of add-on packages.

## Usage

```
read.00Index(file)
```

## Arguments

|      |                                                                                                                                                                                                                                                                                                                        |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file | the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (in this case input can be terminated by a blank line). Alternatively, file can be a <a href="#">connection</a> , which will be opened if necessary, and if so closed at the end of the function call. |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Value

A character matrix with 2 columns named "Item" and "Description" which hold the items and descriptions.

## See Also

[formatDL](#) for the inverse operation of creating a 00Index-style file from items and their descriptions.

showNonASCII

*Pick Out Non-ASCII Characters*

---

**Description**

This function prints elements of a character vector which contain non-ASCII bytes, printing such bytes as a escape like '<fc>'.

**Usage**

```
showNonASCII(x)
```

```
showNonASCIIfile(file)
```

**Arguments**

|      |                     |
|------|---------------------|
| x    | a character vector. |
| file | path to a file.     |

**Details**

This was originally written to help detect non-portable text in files in packages.

It prints all element of x which contain non-ASCII characters, preceded by the element number and with non-ASCII bytes highlighted via `iconv(sub = "byte")`.

**Value**

The elements of x containing non-ASCII characters will be returned invisibly.

**Examples**

```
out <- c(
  "fa\xe7ile test of showNonASCII():",
  "\\details{",
  "  This is a good line",
  "  This has an \xfcmlaut in it.",
  "  OK again.",
  "}")
f <- tempfile()
cat(out, file = f, sep = "\n")

showNonASCIIfile(f)
unlink(f)
```

---

|                  |                                           |
|------------------|-------------------------------------------|
| startDynamicHelp | <i>Start the Dynamic HTML Help System</i> |
|------------------|-------------------------------------------|

---

## Description

This function starts the internal help server, so that HTML help pages are rendered when requested.

## Usage

```
startDynamicHelp(start = TRUE)
```

## Arguments

|       |                                                                                                                      |
|-------|----------------------------------------------------------------------------------------------------------------------|
| start | logical: whether to start or shut down the dynamic help system. If NA, the server is started if not already running. |
|-------|----------------------------------------------------------------------------------------------------------------------|

## Details

This function starts the internal HTTP server, which runs on the loopback interface (127.0.0.1). If `options("help.ports")` is set to a vector of integer values, `startDynamicHelp` will try those ports in order; otherwise, it tries up to 10 random ports to find one not in use. It can be disabled by setting the environment variable `R_DISABLE_HTTPD` to a non-empty value.

`startDynamicHelp` is called by functions that need to use the server, so would rarely be called directly by a user.

Note that `options(help_type = "html")` must be set to actually make use of HTML help, although it might be the default for an R installation.

If the server cannot be started or is disabled, [help.start](#) will be unavailable and requests for HTML help will give text help (with a warning).

The browser in use does need to be able to connect to the loopback interface: occasionally it is set to use a proxy for HTTP on all interfaces, which will not work – the solution is to add an exception for 127.0.0.1.

## Value

The chosen port number is returned invisibly (which will be 0 if the server has been stopped).

## See Also

[help.start](#) and `help(help_type = "html")` will attempt to start the HTTP server if required  
[Rd2HTML](#) is used to render the package help pages.

---

|                 |                                        |
|-----------------|----------------------------------------|
| SweaveTeXFilter | <i>Strip R code out of Sweave file</i> |
|-----------------|----------------------------------------|

---

## Description

This function blanks out code chunks and Noweb markup in an Sweave input file, for spell checking or other uses.

## Usage

```
SweaveTeXFilter(ifile, encoding = "unknown")
```

## Arguments

|                       |                                                      |
|-----------------------|------------------------------------------------------|
| <code>ifile</code>    | Input file or connection.                            |
| <code>encoding</code> | Text encoding to pass to <a href="#">readLines</a> . |

## Details

This function blanks out all Noweb markup and code chunks from an Sweave input file, leaving behind the LaTeX source, so that a LaTeX-aware spelling checker can check it and report errors in their original locations.

## Value

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Sweave input file.

## Author(s)

Duncan Murdoch

## See Also

[aspell](#), for which this is used with `filter = "Sweave"`.

---

testInstalledPackage    *Test Installed Packages*

---

## Description

These functions allow an installed package to be tested, or all base and recommended packages.

## Usage

```
testInstalledPackage(pkg, lib.loc = NULL, outDir = ".",
                     types = c("examples", "tests", "vignettes"),
                     srcdir = NULL, Ropts = "", ...)

testInstalledPackages(outDir = ".", errorsAreFatal = TRUE,
                      scope = c("both", "base", "recommended"),
                      types = c("examples", "tests", "vignettes"),
                      srcdir = NULL, Ropts = "", ...)

testInstalledBasic(scope = c("basic", "devel", "both", "internet"))
```

## Arguments

|                |                                                                                                       |
|----------------|-------------------------------------------------------------------------------------------------------|
| pkg            | name of an installed package.                                                                         |
| lib.loc        | library path(s) in which to look for the package. See <a href="#">library</a> .                       |
| outDir         | the directory into which to write the output files: this should already exist.                        |
| types          | type(s) of tests to be done.                                                                          |
| errorsAreFatal | logical: should testing terminate at the first error?                                                 |
| srcdir         | Optional directory to look for .save files.                                                           |
| Ropts          | Additional options such as ‘-d valgrind’ to be passed to R CMD BATCH when running examples or tests.  |
| ...            | additional arguments use when preparing the files to be run, e.g. commentDontrun and commentDonttest. |
| scope          | Which set(s) should be tested? Can be abbreviated.                                                    |

## Details

These tests depend on having the package example files installed (which is the default). If package-specific tests are found in a ‘tests’ directory they can be tested: these are not installed by default, but will be if R CMD INSTALL --install-tests was used. Finally, the R code in any vignettes can be extracted and tested.

Package tests are run in a ‘pkg-tests’ subdirectory of ‘outDir’, and leave their output there.

testInstalledBasic runs the basic tests, if installed. This should be run with LC\_COLLATE=C set: the function tries to set this by it may not work on all OSes. For non-English locales it may be

desirable to set environment variables LANGUAGE to ‘en’ and LC\_TIME to ‘C’ to reduce the number of differences from reference results.

Except on Windows, if the environment variable TEST\_MC\_CORES is set to an integer greater than one, testInstalledPackages will run the package tests in parallel using its value as the maximum number of parallel processes.

The package-specific tests for the base and recommended packages are not normally installed, but make install-tests is provided to do so (as well as the basic tests).

**Value**

Invisibly 0L for success, 1L for failure.

---

|          |                            |
|----------|----------------------------|
| texi2dvi | <i>Compile LaTeX Files</i> |
|----------|----------------------------|

---

**Description**

Run latex and bibtex until all cross-references are resolved and create either a dvi or a PDF file.

**Usage**

```
texi2dvi(file, pdf = FALSE, clean = FALSE, quiet = TRUE,
         texi2dvi = getOption("texi2dvi"),
         texinputs = NULL, index = TRUE)
```

```
texi2pdf(file, clean = FALSE, quiet = TRUE,
         texi2dvi = getOption("texi2dvi"),
         texinputs = NULL, index = TRUE)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file      | character string. Name of LaTeX source file.                                                                                                                                                                                                                                                       |
| pdf       | logical. If TRUE, a PDF file is produced instead of the default dvi file (texi2dvi command line option ‘--pdf’).                                                                                                                                                                                   |
| clean     | logical. If TRUE, all auxiliary files created during the conversion are removed.                                                                                                                                                                                                                   |
| quiet     | logical. No output unless an error occurs.                                                                                                                                                                                                                                                         |
| texi2dvi  | character string (or NULL). Script or program used to compile a TeX file to dvi or PDF. The default (selected by "" or NULL) is to look for a program or script named ‘texi2dvi’ on the path and otherwise emulate the script with system2 calls (which can be selected by the value "emulation"). |
| texinputs | NULL or a character vector of paths to add to the LaTeX and bibtex input search paths.                                                                                                                                                                                                             |
| index     | logical: should indices be prepared?                                                                                                                                                                                                                                                               |

### Details

`texi2pdf` is a wrapper for the common case of `texi2dvi(pdf = TRUE)`.

Despite the name, this is used in **R** to compile LaTeX files, specifically those generated from vignettes. It ensures that the '`R_HOME/share/texmf`' directory is in the `TEXINPUTS` path, so **R** style files such as 'Sweave' and 'Rd' will be found. The TeX search path used is first the existing `TEXINPUTS` setting (or the current directory if unset), then elements of `texinputs`, then '`R_HOME/share/texmf`' and finally the default path. Analogous changes are made to `BIBINPUTS` and `BSTINPUTS` settings.

The default option for `texi2dvi` is set from environment variable `R_TEXI2DVICMD`, and the default for that is set from environment variable `TEXI2DVI` or if that is unset, from a value chosen when **R** is configured. A shell script `texi2dvi` is part of GNU's **texinfo**.

Occasionally indices contain special characters which cause indexing to fail (particularly when using the 'hyperref' LaTeX package) even on valid input. The argument `index = FALSE` is provided to allow package manuals to be made when this happens: it uses emulation.

### Value

Invisible `NULL`. Used for the side effect of creating a dvi or PDF file in the current working directory (and maybe other files, especially if `clean = FALSE`).

### Note

There are various versions of the `texi2dvi` script on Unix-alikes and quite a number of bugs have been seen, some of which this **R** wrapper works around.

One that was present with `texi2dvi` version 4.8 (as supplied by OS X) is that it will not work correctly for paths which contain spaces, nor if the absolute path to a file would contain spaces.

The three possible approaches all have their quirks. For example the Unix-alike `texi2dvi` script removes ancillary files that already exist but the other two approaches do not (and may get confused by such files).

Where supported (`texi2dvi` 5.0 and later, and `texi2dvi.exe` and `texify.exe` from MiKTeX), option '`--max-iterations=20`' is used to avoid infinite retries.

The emulation mode supports `quiet = TRUE` from **R** 3.2.3 only.

### Author(s)

Originally Achim Zeileis but largely rewritten by R-core.

---

toHTML

*Display an object in HTML.*

---

### Description

This generic function generates a complete HTML page from an object.

**Usage**

```
toHTML(x, ...)
## S3 method for class 'packageIQR'
toHTML(x, ...)
## S3 method for class 'news_db'
toHTML(x, ...)
```

**Arguments**

|     |                                                                                                                    |
|-----|--------------------------------------------------------------------------------------------------------------------|
| x   | An object to display.                                                                                              |
| ... | Optional parameters for methods; the "packageIQR" and "news_db" methods pass these to <a href="#">HTMLheader</a> . |

**Value**

A character vector to display the object x. The "packageIQR" method is designed to display lists in the R help system.

**See Also**

[HTMLheader](#)

**Examples**

```
cat(toHTML(demo(package = "base")), sep = "\n")
```

---

tools-deprecated

*Deprecated Objects in Package **tools***

---

**Description**

The functions or variables listed here are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

**See Also**

[Deprecated](#), [Defunct](#)

|      |                                                                     |
|------|---------------------------------------------------------------------|
| toRd | <i>Generic function to convert object to a fragment of Rd code.</i> |
|------|---------------------------------------------------------------------|

---

### Description

Methods for this function render their associated classes as a fragment of Rd code, which can then be rendered into text, HTML, or LaTeX.

### Usage

```
toRd(obj, ...)
## S3 method for class 'bibentry'
toRd(obj, style = NULL, ...)
```

### Arguments

|       |                                                                       |
|-------|-----------------------------------------------------------------------|
| obj   | The object to be rendered.                                            |
| style | The style to be used in converting a <a href="#">bibentry</a> object. |
| ...   | Additional arguments used by methods.                                 |

### Details

See [bibstyle](#) for a discussion of styles. The default style = NULL value gives the default style.

### Value

Returns a character vector containing a fragment of Rd code that could be parsed and rendered. The default method converts obj to mode character, then escapes any Rd markup within it. The bibentry method converts an object of that class to markup appropriate for use in a bibliography.

---

|             |                                     |
|-------------|-------------------------------------|
| toTitleCase | <i>Convert Titles to Title Case</i> |
|-------------|-------------------------------------|

---

### Description

Convert a character vector to title case, especially package titles.

### Usage

```
toTitleCase(text)
```

### Arguments

|      |                     |
|------|---------------------|
| text | a character vector. |
|------|---------------------|

## Details

This is intended for English text only.

No definition of ‘title case’ is universally accepted: all agree that ‘principal’ words are capitalized and common words like ‘for’ are not, but not which words fall into each category.

Generally words in all capitals are left alone: this implementation knows about conventional mixed-case words such as ‘LaTeX’ and ‘OpenBUGS’ and a few technical terms which are not usually capitalized such as ‘jar’ and ‘xls’. However, unknown technical terms will be capitalized unless they are single words enclosed in single quotes: names of packages and libraries should be quoted in titles.

## Value

A character vector of the same length as `text`, without names.

---

undoc

*Find Undocumented Objects*

---

## Description

Finds the objects in a package which are undocumented, in the sense that they are visible to the user (or data objects or S4 classes provided by the package), but no documentation entry exists.

## Usage

```
undoc(package, dir, lib.loc = NULL)
```

## Arguments

|                      |                                                                                                                                                                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code> | a character string naming an installed package.                                                                                                                                                                                                                    |
| <code>dir</code>     | a character string specifying the path to a package’s root source directory. This must contain the subdirectory ‘man’ with R documentation sources (in Rd format), and at least one of the ‘R’ or ‘data’ subdirectories with R code or data objects, respectively. |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                                                                 |

## Details

This function is useful for package maintainers mostly. In principle, *all* user-level R objects should be documented.

The **base** package is special as it contains the primitives and these do not have definitions available at code level. We provide equivalent closures in environments `.ArgsEnv` and `.GenericArgsEnv` in the **base** package that are used for various purposes: `undoc("base")` checks that all the primitives that are not language constructs are prototyped in those environments and no others are.

**Value**

An object of class "undoc" which is a list of character vectors containing the names of the undocumented objects split according to documentation type.

There is a print method for nicely displaying the information contained in such objects.

**See Also**

[codoc](#), [QC](#)

**Examples**

```
undoc("tools")           # Undocumented objects in 'tools'
```

---

update\_pkg\_po

*Prepare Translations for a Package*

---

**Description**

Prepare the 'po' directory of a package and compile and install the translations.

**Usage**

```
update_pkg_po(pkgdir, pkg = NULL, version = NULL, copyright, bugs)
```

**Arguments**

|                 |                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------|
| pkgdir          | The path to the package directory.                                                                       |
| pkg             | The package name: if NULL it is read from the package's 'DESCRIPTION' file.                              |
| version         | The package version: if NULL it is read from the package's 'DESCRIPTION' file.                           |
| copyright, bugs | optional character strings for the 'Copyright' and 'Report-Msgid-Bugs-To' details in the template files. |

**Details**

This performs a series of steps to prepare or update messages in the package.

- If the package sources do not already have a 'po' directory, one is created.
- [xgettext2pot](#) is called to create/update a file 'po/R-*pkgname*.pot' containing the translatable messages in the package.
- All existing files in directory po with names 'R-*lang*.po' are updated from 'R-*pkgname*.pot', [checkPoFile](#) is called on the updated file, and if there are no problems the file is compiled and installed under 'inst/po'.
- In a UTF-8 locale, a 'translation' 'R-en@quot.po' is created with UTF-8 directional quotes, compiled and installed under 'inst/po'.

- The remaining steps are done only if file `'po/pkgname.pot'` already exists. The `'src/*.{c,cc,cpp,m,mm}'` files in the package are examined to create a file `'po/pkgname.pot'` containing the translatable messages in the C/C++ files. If there is a `src/windows` directory, files within it are also examined.
- All existing files in directory `po` with names `'lang.po'` are updated from `'pkgname.pot'`, [checkPoFile](#) is called on the updated file, and if there are no problems the file is compiled and installed under `'inst/po'`.
- In a UTF-8 locale, a 'translation' `'en@quot.po'` is created with UTF-8 directional quotes, compiled and installed under `'inst/po'`.

Note that C/C++ messages are not automatically prepared for translation as they need to be explicitly marked for translation in the source files. Once that has been done, create an empty file `'po/pkgname.pot'` in the package sources and run this function again.

`pkg = "base"` is special (and for use by R developers only): the C files are not in the package directory but in the main sources.

## System requirements

This function requires the following tools from the GNU `gettext-tools`: `xgettext`, `msgmerge`, `msgfmt`, `msginit` and `msgconv`. These are part of most Linux distributions and easily compiled from the sources on Unix-alikes (including OS X). Pre-compiled versions for Windows are available in <https://www.stats.ox.ac.uk/pub/Rtools/goodies/gettext-tools.zip>.

It will probably not work correctly for `en@quot` translations except in a UTF-8 locale, so these are skipped elsewhere.

[xgettext2pot](#).

---

vignetteDepends

*Retrieve Dependency Information for a Vignette*

---

## Description

Given a vignette name, will create a `DependsList` object that reports information about the packages the vignette depends on.

## Usage

```
vignetteDepends(vignette, recursive = TRUE, reduce = TRUE,
                 local = TRUE, lib.loc = NULL)
```

**Arguments**

|           |                                                                        |
|-----------|------------------------------------------------------------------------|
| vignette  | The path to the vignette source                                        |
| recursive | Whether or not to include indirect dependencies                        |
| reduce    | Whether or not to collapse all sets of dependencies to a minimal value |
| local     | Whether or not to search only locally                                  |
| lib.loc   | What libraries to search in locally                                    |

**Details**

If recursive is TRUE, any package that is specified as a dependency will in turn have its dependencies included (and so on), these are known as indirect dependencies. If recursive is FALSE, only the dependencies directly named by the vignette will be used.

If local is TRUE, the system will only look at the user's local machine and not online to find dependencies.

If reduce is TRUE, the system will collapse the fields in the DependsList object such that a minimal set of dependencies are specified (for instance if there was 'foo, foo (>= 1.0.0), foo (>= 1.3.0)', it would only return 'foo (>= 1.3.0)').

**Value**

An object of class "DependsList".

**Author(s)**

Jeff Gentry

**See Also**

**Examples**

```
## This may not be installed, as it requires lattice
gridEx <- system.file("doc", "grid.Rnw", package = "grid")
vignetteDepends(gridEx)
```

---

vignetteEngine

---

*Set or Get a Vignette Processing Engine*

---

**Description**

Vignettes are normally processed by [Sweave](#), but package writers may choose to use a different engine (e.g., one provided by the [knitr](#), [noweb](#) or [R.rsp](#) packages). This function is used by those packages to register their engines, and internally by R to retrieve them.

**Usage**

```
vignetteEngine(name, weave, tangle, pattern = NULL,
               package = NULL, aspell = list())
```

**Arguments**

|         |                                                                                                                                                                                   |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name    | the name of the engine.                                                                                                                                                           |
| weave   | a function to convert vignette source files to LaTeX output.                                                                                                                      |
| tangle  | a function to convert vignette source files to R code.                                                                                                                            |
| pattern | a regular expression pattern for the filenames handled by this engine, or NULL for the default pattern.                                                                           |
| package | the package registering the engine. By default, this is the package calling vignetteEngine.                                                                                       |
| aspell  | a list with element names filter and/or control giving the respective arguments to be used when spell checking the text in the vignette source file with <a href="#">aspell</a> . |

**Details**

If weave is missing, vignetteEngine will return the currently registered engine matching name and package.

If weave is NULL, the specified engine will be deleted.

Other settings define a new engine. The weave and tangle functions must be defined with argument lists compatible with function(file, ...). Currently the ... arguments may include logical argument quiet and character argument encoding; others may be added in future. These are described in the documentation for [Sweave](#) and [Stangle](#).

The weave and tangle functions should return the filename of the output file that has been produced. Currently the weave function, when operating on a file named '<name> <pattern>' must produce a file named '<name>[.](tex|pdf|html)'. The '.tex' files will be processed by pdf<sub>l</sub>atex to produce '.pdf' output for display to the user; the others will be displayed as produced. The tangle function must produce a file named '<name>[.][rRsS]' containing the executable R code from the vignette. The tangle function may support a split = TRUE argument, and then it should produce files named '<name>.\*[.][rRsS]'.

The pattern argument gives a regular expression to match the extensions of files which are to be processed as vignette input files. If set to NULL, the default pattern "[.][RrSs](nw|tex)\$" is used.

**Value**

If the engine is being deleted, NULL. Otherwise a list containing components

|         |                                      |
|---------|--------------------------------------|
| name    | The name of the engine               |

|----------------|--------------------------------|
| write_PACKAGES | <i>Generate PACKAGES files</i> |
|----------------|--------------------------------|

---

**Description**

Generate ‘PACKAGES’ and ‘PACKAGES.gz’ files for a repository of source or Mac/Windows binary packages.

**Usage**

```
write_PACKAGES(dir = ".", fields = NULL,
               type = c("source", "mac.binary", "win.binary"),
               verbose = FALSE, unpacked = FALSE, subdirs = FALSE,
               latestOnly = TRUE, addFiles = FALSE)
```

**Arguments**

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dir      | Character vector describing the location of the repository (directory including source or binary packages) to generate the ‘PACKAGES’ and ‘PACKAGES.gz’ files from and write them to.                                                                                                                                                                                                                                                                                                                                                         |
| fields   | a character vector giving the fields to be used in the ‘PACKAGES’ and ‘PACKAGES.gz’ files in addition to the default ones, or NULL (default). The default corresponds to the fields needed by <a href="#">available.packages</a> : "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Archs", and those fields will always be included, plus the file name in field "File" if addFile = TRUE and the path to the subdirectory in field "Path" if subdirectories are used. |
| type     | Type of packages: currently source ‘.tar.{gz,bz2,xz}’ archives, and OS X or Windows binary (‘.tgz’ or ‘.zip’, respectively) packages are supported. Defaults to "win.binary" on Windows and to "source" otherwise.                                                                                                                                                                                                                                                                                                                            |
| verbose  | logical. Should packages be listed as they are processed?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| unpacked | a logical indicating whether the package contents are available in unpacked form or not (default).                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| subdirs  | either logical (to indicate if subdirectories should be included, recursively) or a character vector of name of subdirectories to include.                                                                                                                                                                                                                                                                                                                                                                                                    |

|            |                                                                                                      |
|------------|------------------------------------------------------------------------------------------------------|
| latestOnly | logical: if multiple versions of a package are available should only the latest version be included? |
| addFiles   | logical: should the filenames be included as field 'File' in the 'PACKAGES' file.                    |

### Details

write\_PACKAGES scans the named directory for R packages, extracts information from each package's 'DESCRIPTION' file, and writes this information into the 'PACKAGES' and 'PACKAGES.gz' files.

Including non-latest versions of packages is only useful if they have less constraining version requirements, so for example latestOnly = FALSE could be used for a source repository when 'foo\_1.0' depends on 'R >= 2.15.0' but 'foo\_0.9' is available which depends on 'R >= 2.11.0'.

Support for repositories with subdirectories and hence for subdirs != FALSE depends on recording a "Path" field in the 'PACKAGES' file.

Support for more general file names (e.g., other types of compression) *via* a "File" field in the 'PACKAGES' file can be used by [download.packages](#). If the file names are not of the standard form, use addFiles = TRUE.

type = "win.binary" uses [unz](#) connections to read all 'DESCRIPTION' files contained in the (zipped) binary packages for Windows in the given directory dir, and builds files 'PACKAGES' and 'PACKAGES.gz' files from this information.

### Value

Invisibly returns the number of packages described in the resulting 'PACKAGES' and 'PACKAGES.gz' files. If 0, no packages were found and no files were written.

### Note

Processing '.tar.gz' archives to extract the 'DESCRIPTION' files is quite slow.

This function can be useful on other OSes to prepare a repository to be accessed by Windows machines, so type = "win.binary" should work on all OSes.

### Author(s)

Uwe Ligges and R-core.

### See Also

See [read.dcf](#) and [write.dcf](#) for reading 'DESCRIPTION' files and writing the 'PACKAGES' and 'PACKAGES.gz' files.

### Examples

```
## Not run:
write_PACKAGES("c:/myFolder/myRepository") # on Windows
write_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
               type = "win.binary") # on Linux

## End(Not run)
```

---

xgettext

---

*Extract Translatable Messages from R Files in a Package*

---

## Description

For each file in the ‘R’ directory (including system-specific subdirectories) of a package, extract the unique arguments passed to [stop](#), [warning](#), [message](#), [gettext](#) and [gettextf](#), or to [ngettext](#).

## Usage

```
xgettext(dir, verbose = FALSE, asCall = TRUE)
```

```
xngettext(dir, verbose = FALSE)
```

```
xgettext2pot(dir, potFile, name = "R", version, bugs)
```

## Arguments

|                     |                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| dir                 | the directory of a source package.                                                                                                  |
| verbose             | logical: should each file be listed as it is processed?                                                                             |
| asCall              | logical: if TRUE each argument is returned whole, otherwise the strings within each argument are extracted.                         |
| potFile             | name of po template file to be produced. Defaults to ‘R- <i>pkgname</i> .pot’ where <i>pkgname</i> is the basename of ‘dir’.        |
| name, version, bugs | as recorded in the template file: version defaults the version number of the currently running R, and bugs to "bugs.r-project.org". |

## Details

Leading and trailing white space (space, tab and linefeed) is removed for calls to `gettext`, `gettextf`, `stop`, `warning`, and `message`, as it is by the internal code that passes strings for translation.

We look to see if these functions were called with `domain = NA` and if so omit the call if `asCall = TRUE`: note that the call might contain a call to `gettext` which would be visible if `asCall = FALSE`.

`xgettext2pot` calls `xgettext` and then `xngettext`, and writes a PO template file for use with the **GNU Gettext** tools. This ensures that the strings for simple translation are unique in the file (as **GNU Gettext** requires), but does not do so for `ngettext` calls (and the rules are not stated in the Gettext manual, but `msgfmt` complains if there is duplication between the sets.).

If applied to the **base** package, this also looks in the ‘.R’ files in ‘[R\\_HOME](#)/share/R’.

**Value**

For `xgettext`, a list of objects of class `"xgettext"` (which has a `print` method), one per source file that potentially contains translatable strings.

For `xngettext`, a list of objects of class `"xngettext"`, which are themselves lists of length-2 character strings.

**See Also**

[update\\_pkg\\_po\(\)](#) which calls `xgettext2pot()`.

**Examples**

```
## Not run: ## in a source-directory build of R:  
xgettext(file.path(R.home(), "src", "library", "splines"))  
  
## End(Not run)
```

adist

*Approximate String Distances*

---

### Description

Compute the approximate string distance between character vectors. The distance is a generalized Levenshtein (edit) distance, giving the minimal possibly weighted number of insertions, deletions and substitutions needed to transform one string into another.

### Usage

```
adist(x, y = NULL, costs = NULL, counts = FALSE, fixed = TRUE,  
      partial = !fixed, ignore.case = FALSE, useBytes = FALSE)
```

## Arguments

|                          |                                                                                                                                                                                                                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | a character vector. <a href="#">Long vectors</a> are not supported.                                                                                                                                                                                                                                   |
| <code>y</code>           | a character vector, or NULL (default) indicating taking <code>x</code> as <code>y</code> .                                                                                                                                                                                                            |
| <code>costs</code>       | a numeric vector or list with names partially matching ‘insertions’, ‘deletions’ and ‘substitutions’ giving the respective costs for computing the Levenshtein distance, or NULL (default) indicating using unit cost for all three possible transformations.                                         |
| <code>counts</code>      | a logical indicating whether to optionally return the transformation counts (numbers of insertions, deletions and substitutions) as the “counts” attribute of the return value.                                                                                                                       |
| <code>fixed</code>       | a logical. If TRUE (default), the <code>x</code> elements are used as string literals. Otherwise, they are taken as regular expressions and <code>partial = TRUE</code> is implied (corresponding to the approximate string distance used by <a href="#">agrep</a> with <code>fixed = FALSE</code> ). |
| <code>partial</code>     | a logical indicating whether the transformed <code>x</code> elements must exactly match the complete <code>y</code> elements, or only substrings of these. The latter corresponds to the approximate string distance used by <a href="#">agrep</a> (by default).                                      |
| <code>ignore.case</code> | a logical. If TRUE, case is ignored for computing the distances.                                                                                                                                                                                                                                      |
| <code>useBytes</code>    | a logical. If TRUE distance computations are done byte-by-byte rather than character-by-character.                                                                                                                                                                                                    |

## Details

The (generalized) Levenshtein (or edit) distance between two strings  $s$  and  $t$  is the minimal possibly weighted number of insertions, deletions and substitutions needed to transform  $s$  into  $t$  (so that the transformation exactly matches  $t$ ). This distance is computed for `partial = FALSE`, currently using a dynamic programming algorithm (see, e.g., [https://en.wikipedia.org/wiki/Levenshtein\\_distance](https://en.wikipedia.org/wiki/Levenshtein_distance)) with space and time complexity  $O(mn)$ , where  $m$  and  $n$  are the lengths of  $s$  and  $t$ , respectively. Additionally computing the transformation sequence and counts is  $O(\max(m, n))$ .

The generalized Levenshtein distance can also be used for approximate (fuzzy) string matching, in which case one finds the substring of  $t$  with minimal distance to the pattern  $s$  (which could be taken as a regular expression, in which case the principle of using the leftmost and longest match applies), see, e.g., [https://en.wikipedia.org/wiki/Approximate\\_string\\_matching](https://en.wikipedia.org/wiki/Approximate_string_matching). This distance is computed for `partial = TRUE` using ‘tre’ by Ville Laurikari (<http://laurikari.net/tre/>) and corresponds to the distance used by [agrep](#). In this case, the given cost values are coerced to integer.

Note that the costs for insertions and deletions can be different, in which case the distance between  $s$  and  $t$  can be different from the distance between  $t$  and  $s$ .

## Value

A matrix with the approximate string distances of the elements of `x` and `y`, with rows and columns corresponding to `x` and `y`, respectively.

If `counts` is TRUE, the transformation counts are returned as the “counts” attribute of this matrix, as a 3-dimensional array with dimensions corresponding to the elements of `x`, the elements of `y`, and the type of transformation (insertions, deletions and substitutions), respectively. Additionally, if `partial = FALSE`, the transformation sequences are returned as the “trafos” attribute of the

return value, as character strings with elements 'M', 'I', 'D' and 'S' indicating a match, insertion, deletion and substitution, respectively. If `partial = TRUE`, the offsets (positions of the first and last element) of the matched substrings are returned as the "offsets" attribute of the return value (with both offsets `-1` in case of no match).

### See Also

[agrep](#) for approximate string matching (fuzzy matching) using the generalized Levenshtein distance.

### Examples

```
## Cf. https://en.wikipedia.org/wiki/Levenshtein_distance
adist("kitten", "sitting")
## To see the transformation counts for the Levenshtein distance:
drop(attr(adist("kitten", "sitting", counts = TRUE), "counts"))
## To see the transformation sequences:
attr(adist(c("kitten", "sitting"), counts = TRUE), "trafos")

## Cf. the examples for agrep:
adist("lasy", "1 lazy 2")
## For a "partial approximate match" (as used for agrep):
adist("lasy", "1 lazy 2", partial = TRUE)
```

---

alarm

*Alert the User*

---

### Description

Gives an audible or visual signal to the user.

### Usage

```
alarm()
```

### Details

`alarm()` works by sending a `"\a"` character to the console. On most platforms this will ring a bell, beep, or give some other signal to the user (unless standard output has been redirected).

It attempts to flush the console (see [flush.console](#)).

### Value

No useful value is returned.

### Examples

```
alarm()
```

---

apropos

*Find Objects by (Partial) Name*

---

## Description

`apropos()` returns a character vector giving the names of all objects in the search list matching `what`.

`find()` is a different user interface to the same task.

## Usage

```
apropos(what, where = FALSE, ignore.case = TRUE, mode = "any")
```

```
find(what, mode = "any", numeric = FALSE, simple.words = TRUE)
```

## Arguments

|                             |                                                                                                                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>what</code>           | character string with name of an object, or more generally a <a href="#">regular expression</a> to match against.                                                                   |
| <code>where, numeric</code> | a logical indicating whether positions in the search list should also be returned                                                                                                   |
| <code>ignore.case</code>    | logical indicating if the search should be case-insensitive, TRUE by default. Note that in R versions prior to 2.5.0, the default was implicitly <code>ignore.case = FALSE</code> . |
| <code>mode</code>           | character; if not "any", only objects whose <a href="#">mode</a> equals <code>mode</code> are searched.                                                                             |
| <code>simple.words</code>   | logical; if TRUE, the <code>what</code> argument is only searched as whole word.                                                                                                    |

## Details

If `mode != "any"` only those objects which are of mode `mode` are considered. If `where` is TRUE, the positions in the search list are returned as the names attribute.

`find` is a different user interface for the same task as `apropos`. However, by default (`simple.words == TRUE`), only full words are searched with [grep](#)(`fixed = TRUE`).

## Value

For `apropos` character vector, sorted by name, possibly with names giving the (numerical) positions on the search path.

For `find`, either a character vector of environment names, or for `numeric = TRUE`, a numerical vector of positions on the search path, with names giving the names of the corresponding environments.

## Author(s)

Kurt Hornik and Martin Maechler (May 1997).

**See Also**

[glob2rx](#) to convert wildcard patterns to regular expressions.

[objects](#) for listing objects from one place, [help.search](#) for searching the help system, [search](#) for the search path.

**Examples**

```
require(stats)

## Not run: apropos("lm")
apropos("GLM")           # more than a dozen
## that may include internal objects starting '.__C__' if
## methods is attached
apropos("GLM", ignore.case = FALSE) # not one
apropos("lq")

cor <- 1:pi
find("cor")              #> ".GlobalEnv"   "package:stats"
find("cor", numeric = TRUE)      # numbers with these names
find("cor", numeric = TRUE, mode = "function") # only the second one
rm(cor)

## Not run: apropos(".", mode="list") # a long list

# need a DOUBLE backslash '\\' (in case you don't see it anymore)
apropos("\\[")

# everything % not diff-able
length(apropos("."))

# those starting with 'pr'
apropos("^pr")

# the 1-letter things
apropos("^[.]")
# the 1-2-letter things
apropos("^[.]?")
# the 2-to-4 letter things
apropos("^[.]{2,4}")

# the 8-and-more letter things
apropos("^[.]{8,}")
table(nchar(apropos("^[.]{8,}")))
```

## Description

Determine positions of approximate string matches.

## Usage

```
aregexec(pattern, text, max.distance = 0.1, costs = NULL,
          ignore.case = FALSE, fixed = FALSE, useBytes = FALSE)
```

## Arguments

|              |                                                                                                                                                                                                      |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pattern      | a non-empty character string or a character string containing a regular expression (for <code>fixed = FALSE</code> ) to be matched. Coerced by <a href="#">as.character</a> to a string if possible. |
| text         | character vector where matches are sought. Coerced by <a href="#">as.character</a> to a character vector if possible.                                                                                |
| max.distance | maximum distance allowed for a match. See <a href="#">agrep</a> .                                                                                                                                    |
| costs        | cost of transformations. See <a href="#">agrep</a> .                                                                                                                                                 |
| ignore.case  | a logical. If TRUE, case is ignored for computing the distances.                                                                                                                                     |
| fixed        | If TRUE, the pattern is matched literally (as is). Otherwise (default), it is matched as a regular expression.                                                                                       |
| useBytes     | a logical. If TRUE comparisons are byte-by-byte rather than character-by-character.                                                                                                                  |

## Details

`aregexec` provides a different interface to approximate string matching than [agrep](#) (along the lines of the interfaces to exact string matching provided by [regexec](#) and [grep](#)).

Note that by default, [agrep](#) performs literal matches, whereas `aregexec` performs regular expression matches.

See [agrep](#) and [adist](#) for more information about approximate string matching and distances.

Comparisons are byte-by-byte if pattern or any element of text is marked as "bytes".

## Value

A list of the same length as `text`, each element of which is either `-1` if there is no match, or a sequence of integers with the starting positions of the match and all substrings corresponding to parenthesized subexpressions of `pattern`, with attribute `"match.length"` an integer vector giving the lengths of the matches (or `-1` for no match).

## See Also

[regmatches](#) for extracting the matched substrings.

## Examples

```
## Cf. the examples for agrep.
x <- c("1 lazy", "1", "1 LAZY")
aregexec("laysy", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2, ignore.case = TRUE)
m <- aregexec("(lay)(sy)", x, max.distance = 2)
regmatches(x, m)
```

---

aspell

*Spell Check Interface*

---

## Description

Spell check given files via Aspell, Hunspell or Ispell.

## Usage

```
aspell(files, filter, control = list(), encoding = "unknown",
       program = NULL, dictionaries = character())
```

## Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                         |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| files        | a character vector with the names of files to be checked.                                                                                                                                                                                                                                                                                                               |
| filter       | an optional filter for processing the files before spell checking, given as either a function (with formals ifile and encoding), or a character string specifying a built-in filter, or a list with the name of a built-in filter and additional arguments to be passed to it. See <b>Details</b> for available filters. If missing or NULL, no filtering is performed. |
| control      | a list or character vector of control options for the spell checker.                                                                                                                                                                                                                                                                                                    |
| encoding     | the encoding of the files. Recycled as needed.                                                                                                                                                                                                                                                                                                                          |
| program      | a character string giving the name (if on the system path) or full path of the spell check program to be used, or NULL (default). By default, the system path is searched for aspell, hunspell and ispell (in that order), and the first one found is used.                                                                                                             |
| dictionaries | a character vector of names or file paths of additional R level dictionaries to use. Elements with no path separator specify R system dictionaries (in subdirectory 'share/dictionaries' of the R home directory). The file extension (currently, only '.rds') can be omitted.                                                                                          |

## Details

The spell check programs employed must support the so-called Ispell pipe interface activated via command line option '-a'. In addition to the programs, suitable dictionaries need to be available. See <http://aspell.net>, <http://hunspell.sourceforge.net/> and <http://lasr.cs>.

[ucla.edu/geoff/ispell.html](http://ucla.edu/geoff/ispell.html), respectively, for obtaining the Aspell, Hunspell and (International) Ispell programs and dictionaries.

The currently available built-in filters are "Rd" (corresponding to `RdTextFilter`), "Sweave" (corresponding to `SweaveTeXFilter`), "R", "pot" and "dcf".

Filter "R" is for R code and extracts the message string constants in calls to `message`, `warning`, `stop`, `packageStartupMessage`, `gettext`, `gettextf`, and `ngettext` (the unnamed string constants for the first five, and `fmt` and `msg1/msg2` string constants, respectively, for the latter two). Filter "pot" is for message string catalog '.pot' files. Both have an argument `ignore` allowing to give regular expressions for parts of message strings to be ignored for spell checking: e.g., using `"[ \\t]'[^']*'[ \\t[:punct:]]"` ignores all text inside single quotes.

Filter "dcf" is for files in Debian Control File format. The fields to keep can be controlled by argument `keep` (a character vector with the respective field names). By default, 'Title' and 'Description' fields are kept.

The print method for the objects returned by `aspell` has an `indent` argument controlling the indentation of the positions of possibly mis-spelled words. The default is 2; Emacs users may find it useful to use an indentation of 0 and visit output in `grep`-mode. It also has a `verbose` argument: when this is true, suggestions for replacements are shown as well.

It is possible to employ additional R level dictionaries. Currently, these are files with extension '.rds' obtained by serializing character vectors of word lists using `saveRDS`. If such dictionaries are employed, they are combined into a single word list file which is then used as the spell checker's personal dictionary (option '-p'): hence, the default personal dictionary is not used in this case.

## Value

A data frame inheriting from `aspell` (which has a useful print method) with the information about possibly mis-spelled words.

*Spell Check Utilities*

---

## Description

Utilities for spell checking packages via Aspell, Hunspell or Ispell.

## Usage

```

aspell_package_Rd_files(dir, drop = c("\\author", "\\references"),
                        control = list(), program = NULL,
                        dictionaries = character())
aspell_package_vignettes(dir,
                        control = list(), program = NULL,
                        dictionaries = character())
aspell_package_R_files(dir, ignore = character(), control = list(),
                      program = NULL, dictionaries = character())
aspell_package_C_files(dir, ignore = character(), control = list(),
                      program = NULL, dictionaries = character())

aspell_write_personal_dictionary_file(x, out, language = "en",
                                     program = NULL)

```

## Arguments

|              |                                                                                                                                                                                                                                                             |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dir          | a character string specifying the path to a package's root directory.                                                                                                                                                                                       |
| drop         | a character vector naming additional Rd sections to drop when selecting text via <a href="#">RdTextFilter</a> .                                                                                                                                             |
| control      | a list or character vector of control options for the spell checker.                                                                                                                                                                                        |
| program      | a character string giving the name (if on the system path) or full path of the spell check program to be used, or NULL (default). By default, the system path is searched for aspell, hunspell and ispell (in that order), and the first one found is used. |
| dictionaries | a character vector of names or file paths of additional R level dictionaries to use. See <a href="#">aspell</a> .                                                                                                                                           |

|                       |                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------|
| <code>ignore</code>   | a character vector with regular expressions to be replaced by blanks when filtering the message strings. |
| <code>x</code>        | a character vector, or the result of a call to <code>aspell()</code> .                                   |
| <code>out</code>      | a character string naming the personal dictionary file to write to.                                      |
| <code>language</code> | a character string indicating a language as used by Aspell.                                              |

## Details

Functions `aspell_package_Rd_files`, `aspell_package_vignettes`, `aspell_package_R_files` and `aspell_package_C_files` perform spell checking on the Rd files, vignettes, R files, and C-level messages of the package with root directory `dir`. They determine the respective files, apply the appropriate filters, and run the spell checker.

See [aspell](#) for details on filters.

The C-level message string are obtained from the `'po/PACKAGE.pot'` message catalog file, with `PACKAGE` the basename of `dir`. See the section on “C-level messages” in “Writing R Extensions” for more information.

When using Aspell, the vignette checking skips parameters and/or options of commands `\Sexpr`, `\citep`, `\code`, `\pkg`, `\proglang` and `\samp`. Further commands can be skipped by adding `--add-tex-command` options to the control argument. E.g., to skip both option and parameter of `\mycmd`, add `--add-tex-command='mycmd op'`.

Suitable values for control, program, dictionaries, drop and ignore can also be specified using a package defaults file which should go as `'defaults.R'` into the `'.aspell'` subdirectory of `dir`, and provides defaults via assignments of suitable named lists, e.g.,

```
vignettes <- list(control = "--add-tex-command='mycmd op'")
```

for vignettes (when using Aspell) and similarly assigning to `Rd_files`, `R_files` and `C_files` for Rd files, R files and C level message defaults.

Maintainers of packages using both English and American spelling will find it convenient to pass control options `'--master=en_US'` and `'--add-extra-dicts=en_GB'` to Aspell and control options `'-d en_US,en_GB'` to Hunspell (provided that the corresponding dictionaries are installed).

Older versions of R had no support for R level dictionaries, and hence provided the function `aspell_write_personal_dictionary_file` to create (spell check) program-specific personal dictionary files from words to be accepted. The new mechanism is to use R level dictionaries, i.e., `'.rds'` files obtained by serializing character vectors of such words using [saveRDS](#). For such dictionaries specified via the package defaults mechanism, elements with no path separator can be R system dictionaries or dictionaries in the `'.aspell'` subdirectory.

|                    |                                                          |
|--------------------|----------------------------------------------------------|
| available.packages | <i>List Available Packages at CRAN-like Repositories</i> |
|--------------------|----------------------------------------------------------|

---

## Description

`available.packages` returns a matrix of details corresponding to packages currently available at one or more repositories. The current list of packages is downloaded over the internet (or copied from a local mirror).

## Usage

```
available.packages(contriburl =
  contrib.url(getOption("repos"), type),
  method, fields = NULL,
  type = getOption("pkgType"),
  filters = NULL)
```

## Arguments

|                         |                                                                                                                                                                                        |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>contriburl</code> | URL(s) of the ‘contrib’ sections of the repositories. Specify this argument only if your repository mirror is incomplete, e.g., because you burned only the ‘contrib’ section on a CD. |
| <code>method</code>     | download method, see <a href="#">download.file</a> .                                                                                                                                   |
| <code>type</code>       | character string, indicate which type of packages: see <a href="#">install.packages</a> .<br>If <code>type = "both"</code> this will use the source repository.                        |
| <code>fields</code>     | a character vector giving the fields to extract from the ‘PACKAGES’ file(s) in addition to the default ones, or NULL (default). Unavailable fields result in NA values.                |
| <code>filters</code>    | a character vector or list or NULL (default). See ‘Details’.                                                                                                                           |

## Details

The list of packages is either copied from a local mirror (specified by a ‘file://’ URI) or downloaded. If downloaded, the list is cached for the R session in a per-repository file in `tempdir()` with a name like

```
repos_http%3a%2f%2fcran.r-project.org%2fsrc%2fcontrib.rds
```

By default, the return value includes only packages whose version and OS requirements are met by the running version of R, and only gives information on the latest versions of packages.

Argument `filters` can be used to select which of the packages on the repositories are reported. It is called with its default value (NULL) by functions such as `install.packages`: this value corresponds to `getOption("available_packages_filters")` and to `c("R_version", "OS_type", "subarch", "duplicates")` if that is unset or set to NULL.

The built-in filters are

"R\_version" Exclude packages whose R version requirements are not met.

"OS\_type" Exclude packages whose OS requirement is incompatible with this version of R: that is exclude Windows-only packages on a Unix-alike platform and *vice versa*.

"subarch" For binary packages, exclude those with compiled code that is not available for the current sub-architecture, e.g. exclude packages only compiled for 32-bit Windows on a 64-bit Windows R.

"duplicates" Only report the latest version where more than one version is available, and only report the first-named repository (in `contrib.url`) with the latest version if that is in more than one repository.

"license/FOSS" Include only packages for which installation can proceed solely based on packages which can be verified as Free or Open Source Software (FOSS, e.g., <https://en.wikipedia.org/wiki/FOSS>) employing the available license specifications. Thus both the package and any packages that it depends on to load need to be *known to be* FOSS.

Note that this does depend on the repository supplying license information.

"license/restricts\_use" Include only packages for which installation can proceed solely based on packages which are known not to restrict use.

"CRAN" Use CRAN versions in preference to versions from other repositories (even if these have a higher version number). This needs to be applied *before* the default "duplicates" filter, so cannot be used with `add = TRUE`.

If all the filters are from this set, then they can be specified as a character vector; otherwise filters should be a list with elements which are character strings, user-defined functions or `add = TRUE` (see below).

User-defined filters are functions which take a single argument, a matrix of the form returned by `available.packages`, and return a matrix consisting of a subset of the rows of the argument.

The special 'filter' `add = TRUE` appends the other elements of the filter list to the default filters.

## Value

A matrix with one row per package, row names the package names and column names including "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "File" and "Repository". Additional columns can be specified using the `fields` argument.

Where provided by the repository, fields "OS\_type", "License", "License\_is\_FOSS", "License\_restricts\_use", "Archs", "MD5sum" and "NeedsCompilation" are reported for use by the filters and package management tools, including [install.packages](#).

## Examples

```
## Not run:
## Restrict install.packages() (etc) to known-to-be-FOSS packages
options(available_packages_filters =
  c("R_version", "OS_type", "subarch", "duplicates", "license/FOSS"))
```

```
## or
options(available_packages_filters = list(add = TRUE, "license/FOSS"))

## Give priority to released versions on CRAN, rather than development
## versions on Omegahat, R-Forge etc.
options(available_packages_filters =
  c("R_version", "OS_type", "subarch", "CRAN", "duplicates"))

## End(Not run)
```

BATCH

*Batch Execution of R***Description**

Run R non-interactively with input from infile and send output (stdout/stderr) to another file.

**Usage**

R CMD BATCH [options] infile [outfile]

**Arguments**

|         |                                                                                                                                                                                                                                                                                      |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| infile  | the name of a file with R code to be executed.                                                                                                                                                                                                                                       |
| options | a list of R command line options, e.g., for setting the amount of memory available and controlling the load/save process. If infile starts with a '-', use '--' as the final option. The default options are '--restore --save --no-readline'. (Without '--no-readline' on Windows.) |
| outfile | the name of a file to which to write output. If not given, the name used is that of infile, with a possible '.R' extension stripped, and '.Rout' appended.                                                                                                                           |

**Details**

Use R CMD BATCH --help to be reminded of the usage.

By default, the input commands are printed along with the output. To suppress this behavior, add options(echo = FALSE) at the beginning of infile, or use option '--slave'.

The infile can have end of line marked by LF or CRLF (but not just CR), and files with an incomplete last line (missing end of line (EOL) mark) are processed correctly.

A final expression 'proc.time()' will be executed after the input script unless the latter calls q(runLast = FALSE) or is aborted. This can be suppressed by the option '--no-timing'.

Additional options can be set by the environment variable R\_BATCH\_OPTIONS: these come after the default options (see the description of the options argument) and before any options given on the command line.

**Note**

Unlike `Splus BATCH` on a Unix-alike, this does not run the `R` process in the background. In most shells,

```
R CMD BATCH [options] infile [outfile] &
```

will do so.

---

 bibentry

*Bibliography Entries*

---

**Description**

Functionality for representing and manipulating bibliographic information in enhanced BibTeX style.

**Usage**

```
bibentry(bibtype, textVersion = NULL, header = NULL, footer = NULL,
         key = NULL, ..., other = list(),
         mheader = NULL, mfooter = NULL)
## S3 method for class 'bibentry'
print(x, style = "text", .bibstyle, ...)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bibtype</code>     | a character string with a BibTeX entry type. See <b>Entry Types</b> for details.                                                                                                                                                                                                                                                    |
| <code>textVersion</code> | a character string with a text representation of the reference to optionally be employed for printing.                                                                                                                                                                                                                              |
| <code>header</code>      | a character string with optional header text.                                                                                                                                                                                                                                                                                       |
| <code>footer</code>      | a character string with optional footer text.                                                                                                                                                                                                                                                                                       |
| <code>key</code>         | a character string giving the citation key for the entry.                                                                                                                                                                                                                                                                           |
| <code>...</code>         | for <code>bibentry</code> : arguments of the form <i>tag=value</i> giving the fields of the entry, with <i>tag</i> and <i>value</i> the name and value of the field, respectively. Arguments with empty values are dropped. See <b>Entry Fields</b> for details.<br>For the print method, extra parameters to pass to the renderer. |
| <code>other</code>       | a list of arguments as in <code>...</code> (useful in particular for fields named the same as <code>formals</code> of <code>bibentry</code> ).                                                                                                                                                                                      |
| <code>mheader</code>     | a character string with optional “outer” header text.                                                                                                                                                                                                                                                                               |
| <code>mfooter</code>     | a character string with optional “outer” footer text.                                                                                                                                                                                                                                                                               |
| <code>x</code>           | an object inheriting from class “ <code>bibentry</code> ”.                                                                                                                                                                                                                                                                          |
| <code>style</code>       | an optional character string specifying the print style. If present, must be a unique abbreviation (with case ignored) of the available styles, see <b>Details</b> .                                                                                                                                                                |
| <code>.bibstyle</code>   | a character string naming a bibliography style.                                                                                                                                                                                                                                                                                     |

## Details

The bibentry objects created by bibentry can represent an arbitrary positive number of references. One can use `c()` to combine bibentry objects, and hence in particular build a multiple reference object from single reference ones. Alternatively, one can use bibentry to directly create a multiple reference object by “vectorizing” the given arguments, i.e., use character vectors instead of character strings.

The `print` method for bibentry objects provides a choice between seven different styles: plain text (style “text”), BibTeX (“Bibtex”), a mixture of plain text and BibTeX as traditionally used for citations (“citation”), HTML (“html”), LaTeX (“latex”), R code (“R”), and a simple copy of the textVersion elements (style “textVersion”). The “text”, “html” and “latex” styles make use of the `.bibstyle` argument using the `bibstyle` function. When printing bibentry objects in citation style, a header/footer for each item can be displayed as well as a mheader/mfooter for the whole vector of references.

The `print` method is based on a `format` method which provides the same styles, and for formatting as R code a choice between giving a character vector with one bibentry() call for each bibentry (as commonly used in ‘CITATION’ files), or a character string with one collapsed call, obtained by combining the individual calls with `c()` if there is more than one bibentry. This can be controlled by setting the option `collapse` to FALSE (default) or TRUE, respectively. (Printing in R style always collapses to a single call.) Further, for the “citation” style, `format()`’s optional argument `citation.bibtex.max` (with default `getOption("citation.bibtex.max")` which defaults to 1) determines for up to how many citation bibentries text style is shown together with with bibtex, automatically.

It is possible to subscript bibentry objects by their keys (which are used for character subscripts if the names are NULL).

There is also a `toBibtex` method for direct conversion to BibTeX.

## Value

bibentry produces an object of class “bibentry”.

## Entry Types

bibentry creates “bibentry” objects, which are modeled after BibTeX entries. The entry should be a valid BibTeX entry type, e.g.,

**Article:** An article from a journal or magazine.

**Book:** A book with an explicit publisher.

**InBook:** A part of a book, which may be a chapter (or section or whatever) and/or a range of pages.

**InCollection:** A part of a book having its own title.

**InProceedings:** An article in a conference proceedings.

**Manual:** Technical documentation like a software manual.

**MastersThesis:** A Master’s thesis.

**Misc:** Use this type when nothing else fits.

**PhdThesis:** A PhD thesis.

**Proceedings:** The proceedings of a conference.

**TechReport:** A report published by a school or other institution, usually numbered within a series.

**Unpublished:** A document having an author and title, but not formally published.

## Entry Fields

The ... argument of `bibentry` can be any number of BibTeX fields, including

**address:** The address of the publisher or other type of institution.

**author:** The name(s) of the author(s), either as a character string in the format described in the LaTeX book, or a [person](#) object.

**booktitle:** Title of a book, part of which is being cited.

**chapter:** A chapter (or section or whatever) number.

**doi:** The DOI ([https://en.wikipedia.org/wiki/Digital\\_Object\\_Identifier](https://en.wikipedia.org/wiki/Digital_Object_Identifier)) for the reference.

**editor:** Name(s) of editor(s), same format as author.

**institution:** The publishing institution of a technical report.

**journal:** A journal name.

**note:** Any additional information that can help the reader. The first word should be capitalized.

**number:** The number of a journal, magazine, technical report, or of a work in a series.

**pages:** One or more page numbers or range of numbers.

**publisher:** The publisher's name.

**school:** The name of the school where a thesis was written.

**series:** The name of a series or set of books.

**title:** The work's title.

**url:** A URL for the reference. (If the URL is an expanded DOI, we recommend to use the 'doi' field with the unexpanded DOI instead.)

**volume:** The volume of a journal or multi-volume book.

**year:** The year of publication.

browseEnv

*Browse Objects in Environment*

---

## Description

The browseEnv function opens a browser with list of objects currently in sys.frame() environment.

## Usage

```
browseEnv(envir = .GlobalEnv, pattern,
          excludepatt = "^last\\.warning",
          html = .Platform$GUI != "AQUA",
          expanded = TRUE, properties = NULL,
          main = NULL, debugMe = FALSE)
```

## Arguments

|             |                                                                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| envir       | an <a href="#">environment</a> the objects of which are to be browsed.                                                                                          |
| pattern     | a <a href="#">regular expression</a> for object subselection is passed to the internal <code>ls()</code> call.                                                  |
| excludepatt | a regular expression for <i>dropping</i> objects with matching names.                                                                                           |
| html        | is used to display the workspace on a HTML page in your favorite browser. The default except when running from R. app on OS X.                                  |
| expanded    | whether to show one level of recursion. It can be useful to switch it to FALSE if your workspace is large. This option is ignored if html is set to FALSE.      |
| properties  | a named list of global properties (of the objects chosen) to be showed in the browser; when NULL (as per default), user, date, and machine information is used. |
| main        | a title string to be used in the browser; when NULL (as per default) a title is constructed.                                                                    |
| debugMe     | logical switch; if true, some diagnostic output is produced.                                                                                                    |

## Details

Very experimental code: displays a static HTML page on all platforms except R. app on OS X.

Only allows one level of recursion into object structures.

It can be generalized. See sources for details. Most probably, this should rather work through using the `tkWidget` package (from <https://www.bioconductor.org>).

**See Also**[str](#), [ls](#).**Examples**

```

if(interactive()) {
  ## create some interesting objects :
  ofa <- ordered(4:1)
  ex1 <- expression(1+ 0:9)
  ex3 <- expression(u, v, 1+ 0:9)
  example(factor, echo = FALSE)
  example(table, echo = FALSE)
  example(ftable, echo = FALSE)
  example(lm, echo = FALSE, ask = FALSE)
  example(str, echo = FALSE)

  ## and browse them:
  browseEnv()

  ## a (simple) function's environment:
  af12 <- approxfun(1:2, 1:2, method = "const")
  browseEnv(envir = environment(af12))
}

```

browseURL

*Load URL into an HTML Browser***Description**

Load a given URL into an HTML browser.

**Usage**

```

browseURL(url, browser = getOption("browser"),
          encodeIfNeeded = FALSE)

```

**Arguments**

|                |                                                                                                                                                                                                                                                                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| url            | a non-empty character string giving the URL to be loaded.                                                                                                                                                                                                                                                                                        |
| browser        | a non-empty character string giving the name of the program to be used as the HTML browser. It should be in the PATH, or a full path specified. Alternatively, an R function to be called to invoke the browser.<br>Under Windows NULL is also allowed (and is the default), and implies that the file association mechanism will be used.       |
| encodeIfNeeded | Should the URL be encoded by <a href="#">URLencode</a> before passing to the browser? This is not needed (and might be harmful) if the browser program/function itself does encoding, and can be harmful for 'file://' URLs on some systems and for 'http://' URLs passed to some CGI applications. Fortunately, most URLs do not need encoding. |

## Details

The default browser is set by option "browser", in turn set by the environment variable R\_BROWSER which is by default set in file '[R\\_HOME](#)/etc/Renviron' to a choice made manually or automatically when R was configured. (See [Startup](#) for where to override that default value.) To suppress showing URLs altogether, use the value "false".

On many platforms it is best to set option "browser" to a generic program/script and let that invoke the user's choice of browser. For example, on OS X use open and on many other Unix-alikes use xdg-open.

If browser supports remote control and R knows how to perform it, the URL is opened in any already-running browser or a new one if necessary. This mechanism currently is available for browsers which support the "-remote openURL(...)" interface (which includes Mozilla and Opera), Galeon, KDE konqueror (*via* kfmclient) and the GNOME interface to Mozilla. (Firefox has dropped support, but defaults to using an already-running browser.) Note that the type of browser is determined from its name, so this mechanism will only be used if the browser is installed under its canonical name.

Because "-remote" will use any browser displaying on the X server (whatever machine it is running on), the remote control mechanism is only used if DISPLAY points to the local host. This may not allow displaying more than one URL at a time from a remote host.

It is the caller's responsibility to encode url if necessary (see [URLencode](#)). This can be tricky for file URLs, where the format accepted can depend on both browser and OS.

To suppress showing URLs altogether, set browser = "false".

The behaviour for arguments url which are not URLs is platform-dependent. Some platforms accept absolute file paths; fewer accept relative file paths.

## Examples

```
## Not run: ## for KDE users who want to open files in a new tab
options(browser = "kfmclient newTab")
browseURL("https://www.r-project.org")

## End(Not run)
```

---

browseVignettes

*List Vignettes in an HTML Browser*

---

## Description

List available vignettes in an HTML browser with links to PDF, LaTeX/noweb source, and (tangled) R code (if available).

## Usage

```
browseVignettes(package = NULL, lib.loc = NULL, all = TRUE)

## S3 method for class 'browseVignettes'
print(x, ...)
```

### Arguments

|         |                                                                                                                                             |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character vector with the names of packages to search through, or NULL in which "all" packages (as defined by argument all) are searched. |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.      |
| all     | logical; if TRUE search all available packages in the library trees specified by lib.loc, and if FALSE, search only attached packages.      |
| x       | Object of class browseVignettes.                                                                                                            |
| ...     | Further arguments, ignored by the print method.                                                                                             |

### Details

Function browseVignettes returns an object of the same class; the print method displays it as an HTML page in a browser (using [browseURL](#)).

### See Also

[browseURL](#), [vignette](#)

### Examples

```
## List vignettes from all *attached* packages
browseVignettes(all = FALSE)

## List vignettes from a specific package
browseVignettes("grid")
```

---

bug.report

*Send a Bug Report*

---

### Description

Invokes an editor or email program to write a bug report or opens a web page for bug submission. Some standard information on the current version and configuration of R are included automatically.

### Usage

```
bug.report(subject = "", address,
            file = "R.bug.report", package = NULL, lib.loc = NULL,
            ...)
```

## Arguments

|         |                                                                                                                                                                                    |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| subject | Subject of the email.                                                                                                                                                              |
| address | Recipient's email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).  |
| file    | filename to use (if needed) for setting up the email.                                                                                                                              |
| package | Optional character vector naming a single package which is the subject of the bug report.                                                                                          |
| lib.loc | A character vector describing the location of R library trees in which to search for the package, or NULL. The default value of NULL corresponds to all libraries currently known. |
| ...     | additional named arguments such as method and ccaddress to pass to <a href="#">create.post</a> .                                                                                   |

## Details

If package is NULL or a base package, this opens the R bugs tracker at <https://bugs.r-project.org/>.

If package is specified, it is assumed that the bug report is about that package, and parts of its 'DESCRIPTION' file are added to the standard information. If the package has a BugReports field in the 'DESCRIPTION' file, that URL will be opened using [browseURL](#), otherwise an email directed to the package maintainer will be generated using [create.post](#).

## Value

Nothing useful.

## When is there a bug?

If R executes an illegal instruction, or dies with an operating system error message that indicates a problem in the program (as opposed to something like "disk full"), then it is certainly a bug.

Taking forever to complete a command can be a bug, but you must make certain that it was really R's fault. Some commands simply take a long time. If the input was such that you KNOW it should have been processed quickly, report a bug. If you don't know whether the command should take a long time, find out by looking in the manual or by asking for assistance.

If a command you are familiar with causes an R error message in a case where its usual definition ought to be reasonable, it is probably a bug. If a command does the wrong thing, that is a bug. But be sure you know for certain what it ought to have done. If you aren't familiar with the command, or don't know for certain how the command is supposed to work, then it might actually be working right. Rather than jumping to conclusions, show the problem to someone who knows for certain.

Finally, a command's intended definition may not be best for statistical analysis. This is a very important sort of problem, but it is also a matter of judgement. Also, it is easy to come to such a conclusion out of ignorance of some of the existing features. It is probably best not to complain about such a problem until you have checked the documentation in the usual ways, feel confident that you understand it, and know for certain that what you want is not available. The mailing list [r-devel@r-project.org](mailto:r-devel@r-project.org) is a better place for discussions of this sort than the bug list.

If you are not sure what the command is supposed to do after a careful reading of the manual this indicates a bug in the manual. The manual's job is to make everything clear. It is just as important to report documentation bugs as program bugs.

If the online argument list of a function disagrees with the manual, one of them must be wrong, so report the bug.

### How to report a bug

When you decide that there is a bug, it is important to report it and to report it in a way which is useful. What is most useful is an exact description of what commands you type, from when you start R until the problem happens. Always include the version of R, machine, and operating system that you are using; type `version` in R to print this. To help us keep track of which bugs have been fixed and which are still open please send a separate report for each bug.

The most important principle in reporting a bug is to report FACTS, not hypotheses or categorizations. It is always easier to report the facts, but people seem to prefer to strain to posit explanations and report them instead. If the explanations are based on guesses about how R is implemented, they will be useless; we will have to try to figure out what the facts must have been to lead to such speculations. Sometimes this is impossible. But in any case, it is unnecessary work for us.

For example, suppose that on a data set which you know to be quite large the command `data.frame(x, y, z, monday, tuesday)` never returns. Do not report that `data.frame()` fails for large data sets. Perhaps it fails when a variable name is a day of the week. If this is so then when we got your report we would try out the `data.frame()` command on a large data set, probably with no day of the week variable name, and not see any problem. There is no way in the world that we could guess that we should try a day of the week variable name.

Or perhaps the command fails because the last command you used was a `[]` method that had a bug causing R's internal data structures to be corrupted and making the `data.frame()` command fail from then on. This is why we need to know what other commands you have typed (or read from your startup file).

It is very useful to try and find simple examples that produce apparently the same bug, and somewhat useful to find simple examples that might be expected to produce the bug but actually do not. If you want to debug the problem and find exactly what caused it, that is wonderful. You should still report the facts as well as any explanations or solutions.

Invoking R with the `--vanilla` option may help in isolating a bug. This ensures that the site profile and saved data files are not read.

A bug report can be generated using the function `bug.report()`. For reports on R this will open the Web page at <https://bugs.r-project.org/>: for a contributed package it will open the package's bug tracker Web page or help you compose an email to the maintainer.

Bug reports on **contributed packages** should not be sent to the R bug tracker: rather make use of the package argument.

### Author(s)

This help page is adapted from the Emacs manual and the R FAQ

---

capture.output

*Send Output to a Character String or File*

---

**Description**

Evaluates its arguments with the output being returned as a character string or sent to a file. Related to [sink](#) in the same way that [with](#) is related to [attach](#).

**Usage**

```
capture.output(..., file = NULL, append = FALSE,
               type = c("output", "message"), split = FALSE)
```

**Arguments**

|                          |                                                                                                                                                                                               |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code>         | Expressions to be evaluated.                                                                                                                                                                  |
| <code>file</code>        | A file name or a <a href="#">connection</a> , or <code>NULL</code> to return the output as a character vector. If the connection is not open, it will be opened initially and closed on exit. |
| <code>append</code>      | logical. If <code>file</code> a file name or unopened connection, append or overwrite?                                                                                                        |
| <code>type, split</code> | are passed to <a href="#">sink()</a> , see there.                                                                                                                                             |

**Details**

An attempt is made to write output as far as possible to `file` if there is an error in evaluating the expressions, but for `file = NULL` all output will be lost.

Messages sent to [stderr\(\)](#) (including those from [message](#), [warning](#) and [stop](#)) are captured by `type = "message"`. Note that this can be “unsafe” and should only be used with care.

**Value**

A character string (if `file = NULL`), or invisible `NULL`.

**See Also**

[sink](#), [textConnection](#)

## Examples

```
require(stats)
glmout <- capture.output(summary(glm(case ~ spontaneous+induced,
                                     data = infert, family = binomial()))))

glmout[1:5]
capture.output(1+1, 2+2)
capture.output({1+1; 2+2})

## Not run: ## on Unix-alike with a2ps available
op <- options(useFancyQuotes=FALSE)
pdf <- pipe("a2ps -o - | ps2pdf - tempout.pdf", "w")
capture.output(example(glm), file = pdf)
close(pdf); options(op) ; system("evince tempout.pdf &")

## End(Not run)
```

---

|              |                                        |
|--------------|----------------------------------------|
| changedFiles | <i>Detect which files have changed</i> |
|--------------|----------------------------------------|

---

## Description

fileSnapshot takes a snapshot of a selection of files, recording summary information about each. changedFiles compares two snapshots, or compares one snapshot to the current state of the file system. The snapshots need not be the same directory; this could be used to compare two directories.

## Usage

```
fileSnapshot(path = ".", file.info = TRUE, timestamp = NULL,
             md5sum = FALSE, digest = NULL, full.names = length(path) > 1,
             ...)

changedFiles(before, after, path = before$path, timestamp = before$timestamp,
             check.file.info = c("size", "isdir", "mode", "mtime"),
             md5sum = before$md5sum, digest = before$digest,
             full.names = before$full.names, ...)

## S3 method for class 'fileSnapshot'
print(x, verbose = FALSE, ...)

## S3 method for class 'changedFiles'
print(x, verbose = FALSE, ...)
```

## Arguments

|           |                                                                            |
|-----------|----------------------------------------------------------------------------|
| path      | character vector; the path(s) to record.                                   |
| file.info | logical; whether to record <a href="#">file.info</a> values for each file. |

|                 |                                                                                                                                                                                                                           |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| timestamp       | character string or NULL; the name of a file to write at the time the snapshot is taken. This gives a quick test for modification, but may be unreliable; see the Details.                                                |
| md5sum          | logical; whether MD5 summaries of each file should be taken as part of the snapshot.                                                                                                                                      |
| digest          | a function or NULL; a function with header function(filename) which will take a vector of filenames and produce a vector of values of the same length, or a matrix with that number of rows.                              |
| full.names      | logical; whether full names (as in <code>list.files</code> ) should be recorded. Must be TRUE if <code>length(path) &gt; 1</code> .                                                                                       |
| ...             | additional parameters to pass to <code>list.files</code> to control the set of files in the snapshots.                                                                                                                    |
| before, after   | objects produced by <code>fileSnapshot</code> ; two snapshots to compare. If after is missing, a new snapshot of the current file system will be produced for comparison, using arguments recorded in before as defaults. |
| check.file.info | character vector; which columns from <code>file.info</code> should be compared.                                                                                                                                           |
| x               | the object to print.                                                                                                                                                                                                      |
| verbose         | logical; whether to list all data when printing.                                                                                                                                                                          |

## Details

The `fileSnapshot` function uses `list.files` to obtain a list of files, and depending on the `file.info`, `md5sum`, and `digest` arguments, records information about each file.

The `changedFiles` function compares two snapshots.

If the `timestamp` argument to `fileSnapshot` is length 1, a file with that name is created. If it is length 1 in `changedFiles`, the `file_test` function is used to compare the age of all files common to both before and after to it. This test may be unreliable: it compares the current modification time of the after files to the timestamp; that may not be the same as the modification time when the after snapshot was taken. It may also give incorrect results if the clock on the file system holding the timestamp differs from the one holding the snapshot files.

If the `check.file.info` argument contains a non-empty character vector, the indicated columns from the result of a call to `file.info` will be compared.

If `md5sum` is TRUE, `fileSnapshot` will call the `tools::md5sum` function to record the 32 byte MD5 checksum for each file, and `changedFiles` will compare the values. The `digest` argument allows users to provide their own digest function.

## Value

`fileSnapshot` returns an object of class "fileSnapshot". This is a list containing the fields

|      |                                                                                                      |
|------|------------------------------------------------------------------------------------------------------|
| info | a data frame whose rownames are the filenames, and whose columns contain the requested snapshot data |
| path | the normalized path from the call                                                                    |

timestamp, file.info, md5sum, digest, full.names  
                     a record of the other arguments from the call

args                    other arguments passed via ... to [list.files](#).

changedFiles produces an object of class "changedFiles". This is a list containing

added, deleted, changed, unchanged  
                     character vectors of filenames from the before and after snapshots, with obvious meanings

changes                a logical matrix with a row for each common file, and a column for each comparison test. TRUE indicates a change in that test.

[print](#) methods are defined for each of these types. The [print](#) method for "fileSnapshot" objects displays the arguments used to produce them, while the one for "changedFiles" displays the added, deleted and changed fields if non-empty, and a submatrix of the changes matrix containing all of the TRUE values.

### Examples

```
# Create some files in a temporary directory
dir <- tempfile()
dir.create(dir)
writeBin(1L, file.path(dir, "file1"))
writeBin(2L, file.path(dir, "file2"))
dir.create(file.path(dir, "dir"))

# Take a snapshot
snapshot <- fileSnapshot(dir, timestamp = tempfile("timestamp"), md5sum=TRUE)

# Change one of the files.
writeBin(3L:4L, file.path(dir, "file2"))

# Display the detected changes. We may or may not see mtime change...
changedFiles(snapshot)
changedFiles(snapshot)$changes
```

| chooseBioCmirror | <i>Select a Bioconductor Mirror</i> |
|------------------|-------------------------------------|

---

## Description

Interact with the user to choose a Bioconductor mirror.

## Usage

```
chooseBioCmirror(graphics = getOption("menu.graphics"), ind = NULL,
                 useHTTPS = getOption("useHTTPS", TRUE),
                 local.only = FALSE)
```

## Arguments

|            |                                                                                                                                                                                                                        |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| graphics   | Logical. If true, use a graphical list: on Windows or the OS X GUI use a list box, and on a Unix-alike use a Tk widget if package <b>tk</b> and an X server are available. Otherwise use a text <a href="#">menu</a> . |
| ind        | Optional numeric value giving which entry to select.                                                                                                                                                                   |
| useHTTPS   | Whether to prefer HTTPS mirrors (see <a href="#">chooseCRANmirror</a> ).                                                                                                                                               |
| local.only | Logical, try to get most recent list from the Bioconductor master or use file on local disk only.                                                                                                                      |

## Details

This sets the [option](#) "BioC\_mirror": it is used before a call to [setRepositories](#). The out-of-the-box default for that option is NULL, which currently corresponds to the mirror <http://bioconductor.org>.

The 'Bioconductor (World-wide)' 'mirror' is a network of mirrors providing reliable world-wide access; other mirrors may provide faster access on a geographically local scale.

ind chooses a row in '[R\\_HOME](#)/doc/BioC\_mirrors.csv', by number.

## Value

None: this function is invoked for its side effect of updating options("BioC\_mirror").

## Note

The online list of mirrors is always accessed using HTTPS. If your build of R does not support HTTPS, R uses the local copy in '[R\\_HOME](#)/doc/BioC\_mirrors.csv'. It can be updated from [https://bioconductor.org/BioC\\_mirrors.csv](https://bioconductor.org/BioC_mirrors.csv).

---

## Description

Interact with the user to choose a CRAN mirror.

## Usage

```
chooseCRANmirror(graphics = getOption("menu.graphics"), ind = NULL,  
                 useHTTPS = getOption("useHTTPS", TRUE),  
                 local.only = FALSE)  
  
getCRANmirrors(all = FALSE, local.only = FALSE)
```

## Arguments

|            |                                                                                                                                                                                                                           |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| graphics   | Logical. If true, use a graphical list: on Windows or the OS X GUI use a list box, and on a Unix-alike use a Tk widget if package <b>tcltk</b> and an X server are available. Otherwise use a text <a href="#">menu</a> . |
| ind        | Optional numeric value giving which entry to select.                                                                                                                                                                      |
| useHTTPS   | Whether to prefer HTTPS mirrors.                                                                                                                                                                                          |
| all        | Logical, get all known mirrors or only the ones flagged as OK.                                                                                                                                                            |
| local.only | Logical, try to get most recent list from the CRAN master or use file on local disk only.                                                                                                                                 |

## Details

A list of mirrors is stored in file '[R\\_HOME](#)/doc/CRAN\_mirrors.csv', but first an on-line list of current mirrors is consulted, and the file copy used only if the on-line list is inaccessible.

This function is called by a Windows GUI menu item and by [contrib.url](#) if it finds the initial dummy value of [options](#)("repos").

The useHTTPS argument defaults to TRUE. With useHTTPS = TRUE, HTTPS mirrors will be offered in preference to HTTP mirrors (which are listed in a sub-menu). If it is set to FALSE, no HTTPS mirrors will be offered. Choosing an HTTPS mirror provides some guarantees on the identity of the site chosen and so is recommended. (However, most but not all R builds support downloading from HTTPS sites.)

ind chooses a row in the list of current mirrors, by number. It is best used with local.only = TRUE and row numbers in '[R\\_HOME](#)/doc/CRAN\_mirrors.csv'.

## Value

None for chooseCRANmirror(), this function is invoked for its side effect of updating [options](#)("repos").

getCRANmirrors() returns a data frame with mirror information.

Note

The online list of mirrors is always accessed using HTTPS. If your build of R does not support HTTPS, R uses the local copy in '[R\\_HOME](#)/doc/CRAN\_mirrors.csv'. It can be updated from [https://cran.r-project.org/CRAN\\_mirrors.csv](https://cran.r-project.org/CRAN_mirrors.csv).

|----------|------------------------------------------------|
| citation | <i>Citing R and R Packages in Publications</i> |
|----------|------------------------------------------------|

---

Description

How to cite R and R packages in publications.

Usage

```
citation(package = "base", lib.loc = NULL, auto = NULL)
readCitationFile(file, meta = NULL)
```

Arguments

|         |                                                                                                                                                                                                                                                                                                            |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string with the name of a single package. An error occurs if more than one package name is given.                                                                                                                                                                                              |
| lib.loc | a character vector with path names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.                                                                                         |
| auto    | a logical indicating whether the default citation auto-generated from the package 'DESCRIPTION' metadata should be used or not, or NULL (default), indicating that a 'CITATION' file is used if it exists, or an object of class " <a href="#">packageDescription</a> " with package metadata (see below). |
| file    | a file name.                                                                                                                                                                                                                                                                                               |
| meta    | a list of package metadata as obtained by <a href="#">packageDescription</a> , or NULL (the default).                                                                                                                                                                                                      |

Details

The R core development team and the very active community of package authors have invested a lot of time and effort in creating R as it is today. Please give credit where credit is due and cite R and R packages when you use them for data analysis.

Execute function `citation()` for information on how to cite the base R system in publications. If the name of a non-base package is given, the function either returns the information contained in the 'CITATION' file of the package or auto-generates citation information. In the latter case the package 'DESCRIPTION' file is parsed, the resulting citation object may be arbitrarily bad, but is quite useful (at least as a starting point) in most cases.

In R  $\geq$  2.14.0, one can use a 'Authors@R' field in 'DESCRIPTION' to provide (R code giving) a [person](#) object with a refined, machine-readable description of the package "authors" (in particular specifying their precise roles). Only those with an author role will be included in the auto-generated citation.

If only one reference is given, the print method for the object returned by `citation()` shows both a text version and a BibTeX entry for it, if a package has more than one reference then only the text versions are shown. The BibTeX versions can be obtained using function `toBibtex()` (see the examples below).

The 'CITATION' file of an R package should be placed in the 'inst' subdirectory of the package source. The file is an R source file and may contain arbitrary R commands including conditionals and computations. Function `readCitationFile()` is used by `citation()` to extract the information in 'CITATION' files. The file is `source()`d by the R parser in a temporary environment and all resulting bibliographic objects (specifically, of class "[bibentry](#)") are collected.

Traditionally, the 'CITATION' file contained zero or more calls to `citHeader`, then one or more calls to `citEntry`, and finally zero or more calls to `citFooter`, where in fact `citHeader` and `citFooter` are simply wrappers to `paste`, with their `...` argument passed on to `paste` as is. The "[bibentry](#)" class makes for improved representation and manipulation of bibliographic information (in fact, the old mechanism is implemented using the new one), and one can write 'CITATION' files using the unified [bibentry](#) interface.

One can include an auto-generated package citation in the 'CITATION' file via `citation(auto = meta)`.

`readCitationFile` makes use of the `Encoding` element (if any) of `meta` to determine the encoding of the file.

## Value

An object inheriting from class "[bibentry](#)".

## See Also

[bibentry](#)

## Examples

```
## the basic R reference
citation()

## references for a package -- might not have these installed
if(nchar(system.file(package = "lattice"))) citation("lattice")
if(nchar(system.file(package = "foreign"))) citation("foreign")

## extract the bibtex entry from the return value
x <- citation()
toBibtex(x)
```

---

cite

---

*Cite a bibliography entry.*

---

## Description

Cite a `bibentry` object in text. The `cite()` function uses the `cite()` function from the default `bibstyle` if present, or `citeNatbib()` if not. `citeNatbib()` uses a style similar to that used by the LaTeX package **natbib**.

## Usage

```
cite(keys, bib, ...)
citeNatbib(keys, bib, textual = FALSE, before = NULL, after = NULL,
            mode = c("authoryear", "numbers", "super"),
            abbreviate = TRUE, longnamesfirst = TRUE,
            bibpunct = c("(", ")", ";", "a", "", ","), previous)
```

## Arguments

|                             |                                                                                                                                         |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>keys</code>           | A character vector of keys of entries to cite. May contain multiple keys in a single entry, separated by commas.                        |
| <code>bib</code>            | A " <code>bibentry</code> " object containing the list of documents in which to find the keys.                                          |
| <code>...</code>            | Additional arguments to pass to the <code>cite()</code> function for the default style.                                                 |
| <code>textual</code>        | Produce a "textual" style of citation, i.e. what <code>\cit tet</code> would produce in LaTeX.                                          |
| <code>before</code>         | Optional text to display before the citation.                                                                                           |
| <code>after</code>          | Optional text to display after the citation.                                                                                            |
| <code>mode</code>           | The "mode" of citation.                                                                                                                 |
| <code>abbreviate</code>     | Whether to abbreviate long author lists.                                                                                                |
| <code>longnamesfirst</code> | If <code>abbreviate == TRUE</code> , whether to leave the first citation long.                                                          |
| <code>bibpunct</code>       | A vector of punctuation to use in the citation, as used in <b>natbib</b> . See the Details section.                                     |
| <code>previous</code>       | A list of keys that have been previously cited, to be used when <code>abbreviate == TRUE</code> and <code>longnamesfirst == TRUE</code> |

## Details

Argument names are chosen based on the documentation for the LaTeX **natbib** package. See that documentation for the interpretation of the `bibpunct` entries.

The entries in `bibpunct` are as follows:

1. The left delimiter.
2. The right delimiter.
3. The separator between references within a citation.

4. An indicator of the “mode”: “n” for numbers, “s” for superscripts, anything else for author-year.
5. Punctuation to go between the author and year.
6. Punctuation to go between years when authorship is suppressed.

Note that if mode is specified, it overrides the mode specification in `bibpunct[4]`. Partial matching is used for mode.

The defaults for `citeNatbib` have been chosen to match the JSS style, and by default these are used in `cite`. See [bibstyle](#) for how to set a different default style.

### Value

A single element character string is returned, containing the citation.

### Author(s)

Duncan Murdoch

### Examples

```
## R reference
rref <- bibentry(
  bibtype = "Manual",
  title = "R: A Language and Environment for Statistical Computing",
  author = person("R Core Team"),
  organization = "R Foundation for Statistical Computing",
  address = "Vienna, Austria",
  year = 2013,
  url = "https://www.R-project.org/",
  key = "R")

## References for boot package and associated book
bref <- c(
  bibentry(
    bibtype = "Manual",
    title = "boot: Bootstrap R (S-PLUS) Functions",
    author = c(
      person("Angelo", "Canty", role = "aut",
        comment = "S original"),
      person(c("Brian", "D."), "Ripley", role = c("aut", "trl", "cre"),
        comment = "R port, author of parallel support",
        email = "ripley@stats.ox.ac.uk")
    ),
    year = "2012",
    note = "R package version 1.3-4",
    url = "https://CRAN.R-project.org/package=boot",
    key = "boot-package"
  ),
  bibentry(
    bibtype = "Book",
```

```

    title = "Bootstrap Methods and Their Applications",
    author = as.person("Anthony C. Davison [aut], David V. Hinkley [aut]"),
    year = "1997",
    publisher = "Cambridge University Press",
    address = "Cambridge",
    isbn = "0-521-57391-2",
    url = "http://statwww.epfl.ch/davison/BMA/",
    key = "boot-book"
  )
)

## Combine and cite
refs <- c(rref, bref)
cite("R, boot-package", refs)

## Cite numerically
savestyle <- tools::getBibstyle()
tools::bibstyle("JSSnumbered", .init = TRUE,
  fmtPrefix = function(paper) paste0("[", paper$.index, "]"),
  cite = function(key, bib, ...)
    citeNatbib(key, bib, mode = "numbers",
      bibpunct = c("[", "]", ";", "n", "", ", "), ...)
)
cite("R, boot-package", refs, textual = TRUE)
refs

## restore the old style
tools::bibstyle(savestyle, .default = TRUE)

```

---

citEntry

*Bibliography Entries (Older Interface)*

---

## Description

Functionality for specifying bibliographic information in enhanced BibTeX style.

## Usage

```

citEntry(entry, textVersion, header = NULL, footer = NULL, ...)
citHeader(...)
citFooter(...)

```

## Arguments

|             |                                                                                                                      |
|-------------|----------------------------------------------------------------------------------------------------------------------|
| entry       | a character string with a BibTeX entry type. See section <b>Entry Types</b> in <a href="#">bibentry</a> for details. |
| textVersion | a character string with a text representation of the reference.                                                      |
| header      | a character string with optional header text.                                                                        |
| footer      | a character string with optional footer text.                                                                        |

... for `citEntry`, arguments of the form `tag=value` giving the fields of the entry, with `tag` and `value` the name and value of the field, respectively. See section **Entry Fields** in [bibentry](#) for details.  
For `citHeader` and `citFooter`, character strings.

### Value

`citEntry` produces an object of class "bibentry".

### See Also

[citation](#) for more information about citing R and R packages and 'CITATION' files; [bibentry](#) for the newer functionality for representing and manipulating bibliographic information.

---

close.socket

*Close a Socket*

---

### Description

Closes the socket and frees the space in the file descriptor table. The port may not be freed immediately.

### Usage

```
close.socket(socket, ...)
```

### Arguments

socket            a socket object  
...               further arguments passed to or from other methods.

### Value

logical indicating success or failure

### Author(s)

Thomas Lumley

### See Also

[make.socket](#), [read.socket](#).

Compiling in support for sockets is optional: see [capabilities](#)("sockets") to see if it is available.

combn

*Generate All Combinations of  $n$  Elements, Taken  $m$  at a Time***Description**

Generate all combinations of the elements of  $x$  taken  $m$  at a time. If  $x$  is a positive integer, returns all combinations of the elements of `seq(x)` taken  $m$  at a time. If argument `FUN` is not `NULL`, applies a function given by the argument to each point. If `simplify` is `FALSE`, returns a list; otherwise returns an [array](#), typically a [matrix](#). ... are passed unchanged to the `FUN` function, if specified.

**Usage**

```
combn(x, m, FUN = NULL, simplify = TRUE, ...)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | vector source for combinations, or integer $n$ for <code>x &lt;- seq_len(n)</code> .                                                                                                                                                                                                                                                                                                                                                               |
| <code>m</code>        | number of elements to choose.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>FUN</code>      | function to be applied to each combination; default <code>NULL</code> means the identity, i.e., to return the combination (vector of length $m$ ).                                                                                                                                                                                                                                                                                                 |
| <code>simplify</code> | logical indicating if the result should be simplified to an <a href="#">array</a> (typically a <a href="#">matrix</a> ); if <code>FALSE</code> , the function returns a <a href="#">list</a> . Note that when <code>simplify = TRUE</code> as by default, the dimension of the result is simply determined from <code>FUN(1st combination)</code> (for efficiency reasons). This will badly fail if <code>FUN(u)</code> is not of constant length. |
| <code>...</code>      | optionally, further arguments to <code>FUN</code> .                                                                                                                                                                                                                                                                                                                                                                                                |

**Details**

Factors  $x$  are accepted from R 3.1.0 (although coincidentally they worked for `simplify = FALSE` in earlier versions).

**Value**

a [list](#) or [array](#), see the `simplify` argument above. In the latter case, the identity `dim(combn(n, m)) == c(m, choose(n, m))` holds.

**Author(s)**

Scott Chasalow wrote the original in 1994 for S; R package **combinat** and documentation by Vince Carey <stvjc@channing.harvard.edu>; small changes by the R core team, notably to return an array in all cases of `simplify = TRUE`, e.g., for `combn(5,5)`.

**References**

Nijenhuis, A. and Wilf, H.S. (1978) *Combinatorial Algorithms for Computers and Calculators*; Academic Press, NY.

**See Also**

[choose](#) for fast computation of the *number* of combinations. [expand.grid](#) for creating a data frame from all combinations of factors or vectors.

**Examples**

```
combn(letters[1:4], 2)
(m <- combn(10, 5, min)) # minimum value in each combination
mm <- combn(15, 6, function(x) matrix(x, 2, 3))
stopifnot(round(choose(10, 5)) == length(m),
           c(2,3, round(choose(15, 6))) == dim(mm))

## Different way of encoding points:
combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)

## Compute support points and (scaled) probabilities for a
## Multivariate-Hypergeometric(n = 3, N = c(4,3,2,1)) p.f.:
# table.mat(t(combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)))

## Assuring the identity
for(n in 1:7)
  for(m in 0:n) stopifnot(is.array(cc <- combn(n, m)),
                        dim(cc) == c(m, choose(n, m)))
```

---

compareVersion

---

*Compare Two Package Version Numbers*

---

**Description**

Compare two package version numbers to see which is later.

**Usage**

```
compareVersion(a, b)
```

**Arguments**

a, b                      Character strings representing package version numbers.

**Details**

R package version numbers are of the form x.y-z for integers x, y and z, with components after x optionally missing (in which case the version number is older than those with the components present).

**Value**

0 if the numbers are equal, -1 if b is later and 1 if a is later (analogous to the C function strcmp).

**See Also**

[package\\_version](#), [library](#), [packageStatus](#).

**Examples**

```
compareVersion("1.0", "1.0-1")
compareVersion("7.2-0", "7.1-12")
```

---

**COMPILE***Compile Files for Use with R*

---

**Description**

Compile given source files so that they can subsequently be collected into a shared object using R CMD SHLIB or an executable program using R CMD LINK.

**Usage**

```
R CMD COMPILE [options] srcfiles
```

**Arguments**

|          |                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| srcfiles | A list of the names of source files to be compiled. Currently, C, C++, Objective C, Objective C++ and Fortran are supported; the corresponding files should have the extensions <code>‘.c’</code> , <code>‘.cc’</code> (or <code>‘.cpp’</code> ), <code>‘.m’</code> , <code>‘.mm’</code> (or <code>‘.M’</code> ), <code>‘.f’</code> and <code>‘.f90’</code> or <code>‘.f95’</code> , respectively. |
| options  | A list of compile-relevant settings, or for obtaining information about usage and version of the utility.                                                                                                                                                                                                                                                                                          |

**Details**

R CMD SHLIB can both compile and link files into a shared object: since it knows what run-time libraries are needed when passed C++, Fortran and Objective C(++) sources, passing source files to R CMD SHLIB is more reliable.

Ratfor is not supported. If you have Ratfor source code, you need to convert it to FORTRAN. (On some Solaris systems mixing Ratfor and FORTRAN code will work.)

Objective C and Objective C++ support is optional and will work only if the corresponding compilers were available at R configure time: their main usage is on OS X.

Compilation arranges to include the paths to the R public C/C++ headers.

As this compiles code suitable for incorporation into a shared object, it generates PIC code: that might occasionally be undesirable for the main code of an executable program.

This is a make-based facility, so will not compile a source file if a newer corresponding `‘.o’` file is present.

**Note**

Some binary distributions of R have COMPILE in a separate bundle, e.g. an R-devel RPM. This is not available on Windows.

**See Also**

---

`contrib.url`*Find Appropriate Paths in CRAN-like Repositories*

---

**Description**

`contrib.url` adds the appropriate type-specific path within a repository to each URL in `repos`.

**Usage**

```
contrib.url(repos, type = getOption("pkgType"))
```

**Arguments**

|                    |                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------|
| <code>repos</code> | character vector, the base URL(s) of the repositories to use.                               |
| <code>type</code>  | character string, indicating which type of packages: see <a href="#">install.packages</a> . |

**Details**

If `type = "both"` this will use the source repository.

**Value**

A character vector of the same length as `repos`.

**See Also**

[setRepositories](#) to set [options\("repos"\)](#), the most common value used for argument `repos`.  
[available.packages](#), [download.packages](#), [install.packages](#).

---

|              |                                            |
|--------------|--------------------------------------------|
| count.fields | <i>Count the Number of Fields per Line</i> |
|--------------|--------------------------------------------|

---

## Description

count.fields counts the number of fields, as separated by sep, in each of the lines of file read.

## Usage

```
count.fields(file, sep = "", quote = "\"\"", skip = 0,
             blank.lines.skip = TRUE, comment.char = "#")
```

## Arguments

|                  |                                                                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file             | a character string naming an ASCII data file, or a <a href="#">connection</a> , which will be opened if necessary, and if so closed at the end of the function call. |
| sep              | the field separator character. Values on each line of the file are separated by this character. By default, arbitrary amounts of whitespace can separate fields.     |
| quote            | the set of quoting characters                                                                                                                                        |
| skip             | the number of lines of the data file to skip before beginning to read data.                                                                                          |
| blank.lines.skip | logical: if TRUE blank lines in the input are ignored.                                                                                                               |
| comment.char     | character: a character vector of length one containing a single character or an empty string.                                                                        |

## Details

This used to be used by [read.table](#) and can still be useful in discovering problems in reading a file by that function.

For the handling of comments, see [scan](#).

Consistent with [scan](#), count.fields allows quoted strings to contain newline characters. In such a case the starting line will have the field count recorded as NA, and the ending line will include the count of all fields from the beginning of the record.

## Value

A vector with the numbers of fields found.

## See Also

[read.table](#)

## Examples

```
cat("NAME", "1:John", "2:Paul", file = "foo", sep = "\n")
count.fields("foo", sep = ":")
unlink("foo")
```

create.post

*Ancillary Function for Preparing Emails and Postings***Description**

An ancillary function used by [bug.report](#) and [help.request](#) to prepare emails for submission to package maintainers or to R mailing lists.

**Usage**

```
create.post(instructions = character(), description = "post",
            subject = "",
            method = getOption("mailer"),
            address = "the relevant mailing list",
            ccaddress = getOption("ccaddress", ""),
            filename = "R.post", info = character())
```

**Arguments**

|              |                                                                                                                                                                                   |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| instructions | Character vector of instructions to put at the top of the template email.                                                                                                         |
| description  | Character string: a description to be incorporated into messages.                                                                                                                 |
| subject      | Subject of the email. Optional except for the "mailx" method.                                                                                                                     |
| method       | Submission method, one of "none", "mailto", "gnudoit", "ess" or (Unix only) "mailx". See 'Details'.                                                                               |
| address      | Recipient's email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed). |
| ccaddress    | Optional email address for copies with the "mailx" and "mailto" methods. Use ccaddress = "" for no copy.                                                                          |
| filename     | Filename to use for setting up the email (or storing it when method is "none" or sending mail fails).                                                                             |
| info         | character vector of information to include in the template email below the 'please do not edit the information below' line.                                                       |

**Details**

What this does depends on the method. The function first creates a template email body.

**none** A file editor (see [file.edit](#)) is opened with instructions and the template email. When this returns, the completed email is in file `file` ready to be read/pasted into an email program.

**mailto** This opens the default email program with a template email (including address, Cc: address and subject) for you to edit and send.

This works where default mailers are set up (usual on OS X and Windows, and where `xdg-open` is available and configured on other Unix-alikes: if that fails it tries the browser set by `R_BROWSER`).

This is the 'factory-fresh' default method.

`mailx` (Unix-alikes only.) A file editor (see [file.edit](#)) is opened with instructions and the template email. When this returns, it is mailed using a Unix command line mail utility such as `mailx`, to the address (and optionally, the Cc: address) given.

`gnudoit` An (X)emacs mail buffer is opened for the email to be edited and sent: this requires the `gnudoit` program to be available. Currently subject is ignored.

`ess` The body of the template email is sent to stdout.

## Value

Invisible NULL.

## See Also

[bug.report](#), [help.request](#).

---

data

*Data Sets*

---

## Description

Loads specified data sets, or list the available data sets.

## Usage

```
data(..., list = character(), package = NULL, lib.loc = NULL,
      verbose = getOption("verbose"), envir = .GlobalEnv)
```

## Arguments

|                      |                                                                                                                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code>     | literal character strings or names.                                                                                                                                                                              |
| <code>list</code>    | a character vector.                                                                                                                                                                                              |
| <code>package</code> | a character vector giving the package(s) to look in for data sets, or NULL.<br>By default, all packages in the search path are used, then the ‘data’ subdirectory (if present) of the current working directory. |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.                                                                           |
| <code>verbose</code> | a logical. If TRUE, additional diagnostics are printed.                                                                                                                                                          |
| <code>envir</code>   | the <a href="#">environment</a> where the data should be loaded.                                                                                                                                                 |

## Details

Currently, four formats of data files are supported:

1. files ending `‘.R’` or `‘.r’` are `source()`d in, with the R working directory changed temporarily to the directory containing the respective file. (data ensures that the **utils** package is attached, in case it had been run *via* `utils::data`.)
2. files ending `‘.RData’` or `‘.rda’` are `load()`ed.
3. files ending `‘.tab’`, `‘.txt’` or `‘.TXT’` are read using `read.table(..., header = TRUE)`, and hence result in a data frame.
4. files ending `‘.csv’` or `‘.CSV’` are read using `read.table(..., header = TRUE, sep = “;”)`, and also result in a data frame.

If more than one matching file name is found, the first on this list is used. (Files with extensions `‘.txt’`, `‘.tab’` or `‘.csv’` can be compressed, with or without further extension `‘.gz’`, `‘.bz2’` or `‘.xz’`.)

The data sets to be loaded can be specified as a set of character strings or names, or as the character vector `list`, or as both.

For each given data set, the first two types (`‘.R’` or `‘.r’`, and `‘.RData’` or `‘.rda’` files) can create several variables in the load environment, which might all be named differently from the data set. The third and fourth types will always result in the creation of a single variable with the same name (without extension) as the data set.

If no data sets are specified, data lists the available data sets. It looks for a new-style data index in the `‘Meta’` or, if this is not found, an old-style `‘00Index’` file in the `‘data’` directory of each specified package, and uses these files to prepare a listing. If there is a `‘data’` area but no index, available data files for loading are computed and included in the listing, and a warning is given: such packages are incomplete. The information about available data sets is returned in an object of class `“packageIQR”`. The structure of this class is experimental. Where the datasets have a different name from the argument that should be used to retrieve them the index will have an entry like `beaver1` (beavers) which tells us that dataset `beaver1` can be retrieved by the call `data(beaver)`.

If `lib.loc` and `package` are both `NULL` (the default), the data sets are searched for in all the currently loaded packages then in the `‘data’` directory (if any) of the current working directory.

If `lib.loc = NULL` but `package` is specified as a character vector, the specified package(s) are searched for first amongst loaded packages and then in the default library/ies (see `.libPaths`).

If `lib.loc` is specified (and not `NULL`), packages are searched for in the specified library/ies, even if they are already loaded from another library.

To just look in the `‘data’` directory of the current working directory, set `package = character(0)` (and `lib.loc = NULL`, the default).

## Value

A character vector of all data sets specified, or information about all available data sets in an object of class `“packageIQR”` if none were specified.

### Good practice

`data()` was originally intended to allow users to load datasets from packages for use in their examples, and as such it loaded the datasets into the workspace `.GlobalEnv`. This avoided having large datasets in memory when not in use. That need has been almost entirely superseded by lazy-loading of datasets.

The ability to specify a dataset by name (without quotes) is a convenience: in programming the datasets should be specified by character strings (with quotes).

Use of `data` within a function without an `envir` argument has the almost always undesirable side-effect of putting an object in the user's workspace (and indeed, of replacing any object of that name already there). It would almost always be better to put the object in the current evaluation environment by `data(..., envir = environment())`. However, two alternatives are usually preferable, both described in the 'Writing R Extensions' manual.

- For sets of data, set up a package to use lazy-loading of data.
- For objects which are system data, for example lookup tables used in calculations within the function, use a file `'R/sysdata.rda'` in the package sources or create the objects by R code at package installation time.

A sometimes important distinction is that the second approach places objects in the namespace but the first does not. So if it is important that the function sees `mytable` as an object from the package, it is system data and the second approach should be used. In the unusual case that a package uses a lazy-loaded dataset as a default argument to a function, that needs to be specified by `::`, e.g., `survival::survexp.us`.

### Note

One can take advantage of the search order and the fact that a `'R'` file will change directory. If raw data are stored in `'mydata.txt'` then one can set up `'mydata.R'` to read `'mydata.txt'` and pre-process it, e.g., using `transform`. For instance one can convert numeric vectors to factors with the appropriate labels. Thus, the `'R'` file can effectively contain a metadata specification for the plaintext formats.

### See Also

[help](#) for obtaining documentation on data sets, [save](#) for *creating* the second (`'rda'`) kind of data, typically the most efficient one.

The 'Writing R Extensions' for considerations in preparing the `'data'` directory of a package.

### Examples

```
require(utils)
data()                                # list all available data sets
try(data(package = "rpart") )         # list the data sets in the rpart package
data(USArrests, "VADeaths")          # load the data sets 'USArrests' and 'VADeaths'
## Not run: ## Alternatively
ds <- c("USArrests", "VADeaths"); data(list = ds)
## End(Not run)
help(USArrests)                       # give information on data set 'USArrests'
```

dataentry

*Spreadsheet Interface for Entering Data***Description**

A spreadsheet-like editor for entering or editing data.

**Usage**

```
data.entry(..., Modes = NULL, Names = NULL)
dataentry(data, modes)
de(..., Modes = list(), Names = NULL)
```

**Arguments**

|                    |                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code>   | A list of variables: currently these should be numeric or character vectors or list containing such vectors.                  |
| <code>Modes</code> | The modes to be used for the variables.                                                                                       |
| <code>Names</code> | The names to be used for the variables.                                                                                       |
| <code>data</code>  | A list of numeric and/or character vectors.                                                                                   |
| <code>modes</code> | A list of length up to that of <code>data</code> giving the modes of (some of) the variables. <code>list()</code> is allowed. |

**Details**

The data entry editor is only available on some platforms and GUIs. Where available it provides a means to visually edit a matrix or a collection of variables (including a data frame) as described in the Notes section.

`data.entry` has side effects, any changes made in the spreadsheet are reflected in the variables. The functions `de`, `de.ncols`, `de.setup` and `de.restore` are designed to help achieve these side effects. If the user passes in a matrix, `X` say, then the matrix is broken into columns before `dataentry` is called. Then on return the columns are collected and glued back together and the result assigned to the variable `X`. If you don't want this behaviour use `dataentry` directly.

The primitive function is `dataentry`. It takes a list of vectors of possibly different lengths and `modes` (the second argument) and opens a spreadsheet with these variables being the columns. The columns of the `dataentry` window are returned as vectors in a list when the spreadsheet is closed.

`de.ncols` counts the number of columns which are supplied as arguments to `data.entry`. It attempts to count columns in lists, matrices and vectors. `de.setup` sets things up so that on return the columns can be regrouped and reassigned to the correct name. This is handled by `de.restore`.

**Value**

`de` and `dataentry` return the edited value of their arguments. `data.entry` invisibly returns a vector of variable names but its main value is its side effect of assigning new version of those variables in the user's workspace.

## Resources

The data entry window responds to X resources of class R\_dataentry. Resources foreground, background and geometry are utilized.

## Note

The details of interface to the data grid may differ by platform and GUI. The following description applies to the X11-based implementation under Unix.

You can navigate around the grid using the cursor keys or by clicking with the (left) mouse button on any cell. The active cell is highlighted by thickening the surrounding rectangle. Moving to the right or down will scroll the grid as needed: there is no constraint to the rows or columns currently in use.

There are alternative ways to navigate using the keys. Return and (keypad) Enter and LineFeed all move down. Tab moves right and Shift-Tab move left. Home moves to the top left.

PageDown or Control-F moves down a page, and PageUp or Control-B up by a page. End will show the last used column and the last few rows used (in any column).

Using any other key starts an editing process on the currently selected cell: moving away from that cell enters the edited value whereas Esc cancels the edit and restores the previous value. When the editing process starts the cell is cleared. In numerical columns (the default) only letters making up a valid number (including -.eE) are accepted, and entering an invalid edited value (such as blank) enters NA in that cell. The last entered value can be deleted using the BackSpace or Del(ete) key. Only a limited number of characters (currently 29) can be entered in a cell, and if necessary only the start or end of the string will be displayed, with the omissions indicated by > or <. (The start is shown except when editing.)

Entering a value in a cell further down a column than the last used cell extends the variable and fills the gap (if any) by NAs (not shown on screen).

The column names can only be selected by clicking in them. This gives a popup menu to select the column type (currently Real (numeric) or Character) or to change the name. Changing the type converts the current contents of the column (and converting from Character to Real may generate NAs.) If changing the name is selected the header cell becomes editable (and is cleared). As with all cells, the value is entered by moving away from the cell by clicking elsewhere or by any of the keys for moving down (only).

New columns are created by entering values in them (and not by just assigning a new name). The mode of the column is auto-detected from the first value entered: if this is a valid number it gives a numeric column. Unused columns are ignored, so adding data in var5 to a three-column grid adds one extra variable, not two.

The Copy button copies the currently selected cell: paste copies the last copied value to the current cell, and right-clicking selects a cell *and* copies in the value. Initially the value is blank, and attempts to paste a blank value will have no effect.

Control-L will refresh the display, recalculating field widths to fit the current entries.

In the default mode the column widths are chosen to fit the contents of each column, with a default of 10 characters for empty columns. you can specify fixed column widths by setting option de.cellwidth to the required fixed width (in characters). (set it to zero to return to variable widths). The displayed width of any field is limited to 600 pixels (and by the window width).

**See Also**

[vi](#), [edit](#): edit uses `dataentry` to edit data frames.

**Examples**

```
# call data entry with variables x and y
## Not run: data.entry(x, y)
```

---

debugger

*Post-Mortem Debugging*

---

**Description**

Functions to dump the evaluation environments (frames) and to examine dumped frames.

**Usage**

```
dump.frames(dumpto = "last.dump", to.file = FALSE)
debugger(dump = last.dump)
```

**Arguments**

|                      |                                                                |
|----------------------|----------------------------------------------------------------|
| <code>dumpto</code>  | a character string. The name of the object or file to dump to. |
| <code>to.file</code> | logical. Should the dump be to an R object or to a file?       |
| <code>dump</code>    | An R dump object created by <code>dump.frames</code> .         |

**Details**

To use post-mortem debugging, set the option `error` to be a call to `dump.frames`. By default this dumps to an R object `last.dump` in the workspace, but it can be set to dump to a file (a dump of the object produced by a call to [save](#)). The dumped object contains the call stack, the active environments and the last error message as returned by [geterrmessage](#).

When dumping to file, `dumpto` gives the name of the dumped object and the file name has `‘.rda’` appended.

A dump object of class `"dump.frames"` can be examined by calling `debugger`. This will give the error message and a list of environments from which to select repeatedly. When an environment is selected, it is copied and the [browser](#) called from within the copy. Note that not all the information in the original frame will be available, e.g. promises which have not yet been evaluated and the contents of any `...` argument.

If `dump.frames` is installed as the error handler, execution will continue even in non-interactive sessions. See the examples for how to dump and then quit.

**Value**

Invisible `NULL`.

**Note**

Functions such as `sys.parent` and `environment` applied to closures will not work correctly inside debugger.

If the error occurred when computing the default value of a formal argument the debugger will report “recursive default argument reference” when trying to examine that environment.

Of course post-mortem debugging will not work if R is too damaged to produce and save the dump, for example if it has run out of workspace.

**References**

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

**See Also**

`browser` for the actions available at the Browse prompt.

`options` for setting error options; `recover` is an interactive debugger working similarly to debugger but directly after the error occurs.

**Examples**

```
## Not run:
options(error = quote(dump.frames("testdump", TRUE)))

f <- function() {
  g <- function() stop("test dump.frames")
  g()
}
f() # will generate a dump on file "testdump.rda"
options(error = NULL)
```

```
## possibly in another R session
load("testdump.rda")
debugger(testdump)
Available environments had calls:
1: f()
2: g()
3: stop("test dump.frames")
```

```

demo

*Demonstrations of R Functionality***Description**

demo is a user-friendly interface to running some demonstration R scripts. demo() gives the list of available topics.

**Usage**

```

demo(topic, package = NULL, lib.loc = NULL,
      character.only = FALSE, verbose = getOption("verbose"),
      echo = TRUE, ask = getOption("demo.ask"),
      encoding = getOption("encoding"))

```

**Arguments**

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| topic          | the topic which should be demonstrated, given as a <a href="#">name</a> or literal character string, or a character string, depending on whether character.only is FALSE (default) or TRUE. If omitted, the list of available topics is displayed.                                                                                                                                                                                                                                                                      |
| package        | a character vector giving the packages to look into for demos, or NULL. By default, all packages in the search path are used.                                                                                                                                                                                                                                                                                                                                                                                           |
| lib.loc        | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.                                                                                                                                                                                                                                                                                                   |
| character.only | logical; if TRUE, use topic as character string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| verbose        | a logical. If TRUE, additional diagnostics are printed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| echo           | a logical. If TRUE, show the R input when sourcing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ask            | a logical (or "default") indicating if <a href="#">devAskNewPage</a> (ask = TRUE) should be called before graphical output happens from the demo code. The value "default" (the factory-fresh default) means to ask if echo == TRUE and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the demo code. If this is evaluated to TRUE and the session is <a href="#">interactive</a> , the user is asked to press RETURN to start. |

encoding      See [source](#). If the package has a declared encoding, that takes preference.

### Details

If no topics are given, demo lists the available demos. The corresponding information is returned in an object of class "packageIQR".

### See Also

[source](#) and [devAskNewPage](#) which are called by demo.

### Examples

```
demo() # for attached packages

## All available demos:
demo(package = .packages(all.available = TRUE))

## Display a demo, pausing between pages
demo(lm.glm, package = "stats", ask = TRUE)

## Display it without pausing
demo(lm.glm, package = "stats", ask = FALSE)

## Not run:
ch <- "scoping"
demo(ch, character = TRUE)

## End(Not run)

## Find the location of a demo
system.file("demo", "lm.glm.R", package = "stats")
```

---

download.file

*Download File from the Internet*

---

### Description

This function can be used to download a file from the Internet.

### Usage

```
download.file(url, destfile, method, quiet = FALSE, mode = "w",
              cacheOK = TRUE,
              extra = getOption("download.file.extra"))
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>url</code>      | A character string naming the URL of a resource to be downloaded.                                                                                                                                                                                                                                        |
| <code>destfile</code> | A character string with the name where the downloaded file is saved. Tilde-expansion is performed.                                                                                                                                                                                                       |
| <code>method</code>   | Method to be used for downloading files. Current download methods are "internal", "wininet" (Windows only) "libcurl", "wget" and "curl", and there is a value "auto": see 'Details' and 'Note'.<br>The method can also be set through the option "download.file.method": see <a href="#">options()</a> . |
| <code>quiet</code>    | If TRUE, suppress status messages (if any), and the progress bar.                                                                                                                                                                                                                                        |
| <code>mode</code>     | character. The mode with which to write the file. Useful values are "w", "wb" (binary), "a" (append) and "ab". Only used for the "internal" method.                                                                                                                                                      |
| <code>cacheOK</code>  | logical. Is a server-side cached value acceptable?                                                                                                                                                                                                                                                       |
| <code>extra</code>    | character vector of additional command-line arguments for the "wget" and "curl" methods.                                                                                                                                                                                                                 |

## Details

The function `download.file` can be used to download a single file as described by `url` from the internet and store it in `destfile`. The `url` must start with a scheme such as 'http://', 'https://', 'ftp://' or 'file://'.

If `method = "auto"` is chosen (the default), method "libcurl" is chosen for 'https://' and 'ftps://' URLs provided [capabilities\("libcurl"\)](#) is true, and the internal method is chosen for 'file://' URLs and for the others provided [capabilities\("http/ftp"\)](#) is true (which it almost always is).

Support for method "libcurl" is optional: use [capabilities\("libcurl"\)](#) to see if it is supported on your build. (It uses an external library of that name (<http://curl.haxx.se/libcurl/>) against which R can be compiled.) It will usually provide (non-blocking) access to 'https://' and 'ftps://' URLs. There is support for simultaneous downloads, so `url` and `destfile` can be character vectors of the same length greater than one. For a single URL and `quiet = FALSE` a progress bar is shown in interactive use.

For methods "wget" and "curl" a system call is made to the tool given by `method`, and the respective program must be installed on your system and be in the search path for executables. They will block all other activity on the R process until they complete: this may make a GUI unresponsive.

`cacheOK = FALSE` is useful for 'http://' and 'https://' URLs: it will attempt to get a copy directly from the site rather than from an intermediate cache. It is used by [available.packages](#).

The "libcurl" and "wget" methods follow 'http://' and 'https://' redirections: the "internal" does not. (For method "curl" use argument `extra = "-L"`. To disable redirection in wget, use `extra = "--max-redirect=0"`.)

Note that 'https://' URLs are not supported by the internal method.

See [url](#) for how 'file://' URLs are interpreted, especially on Windows. The "internal" and "wininet" methods do not percent-decode 'file://' URLs, but the "libcurl" and "curl" methods do: method "wget" does not support them.

Most methods do not percent-encode special characters such as spaces in URLs (see [URLencode](#)), but it seems the "wininet" method does.

The remaining details apply to the "internal", "wininet" and "libcurl" methods only.

The timeout for many parts of the transfer can be set by the option `timeout` which defaults to 60 seconds.

The level of detail provided during transfer can be set by the `quiet` argument and the `internet.info` option: the details depend on the platform and scheme. For the "internal" method setting option `internet.info` to 0 gives all available details, including all server responses. Using 2 (the default) gives only serious messages, and 3 or more suppresses all messages. For the "libcurl" method values of the option less than 2 give verbose output.

A progress bar tracks the transfer. If the file length is known, an equals sign represents 2% of the transfer completed: otherwise a dot represents 10Kb.

Code written to download binary files must use mode = "wb", but the problems incurred by a text transfer will only be seen on Windows.

## Value

An (invisible) integer code, 0 for success and non-zero for failure. For the "wget" and "curl" methods this is the status code returned by the external program. The "internal" method can return 1, but will in most cases throw an error.

## Setting Proxies

The next two paragraphs apply to the internal code only.

Proxies can be specified via environment variables. Setting `no_proxy` to \* stops any proxy being tried. Otherwise the setting of `http_proxy` or `ftp_proxy` (or failing that, the all upper-case version) is consulted and if non-empty used as a proxy site. For FTP transfers, the username and password on the proxy can be specified by `ftp_proxy_user` and `ftp_proxy_password`. The form of `http_proxy` should be `http://proxy.dom.com/` or `http://proxy.dom.com:8080/` where the port defaults to 80 and the trailing slash may be omitted. For `ftp_proxy` use the form `ftp://proxy.dom.com:3128/` where the default port is 21. These environment variables must be set before the download code is first used: they cannot be altered later by calling [Sys.setenv](#).

Usernames and passwords can be set for HTTP proxy transfers via environment variable `http_proxy_user` in the form `user:passwd`. Alternatively, `http_proxy` can be of the form `http://user:pass@proxy.dom.com:8080/` for compatibility with `wget`. Only the HTTP/1.0 basic authentication scheme is supported.

Much the same scheme is supported by method = "libcurl", including `no_proxy`, `http_proxy` and `ftp_proxy`, and for the last two a contents of `[user:password@]machine[:port]` where the parts in brackets are optional. See <http://curl.haxx.se/libcurl/c/libcurl-tutorial.html> for details.

## Secure URLs

Methods which access 'https://' and 'ftps://' URLs should try to verify their certificates. This is usually done using the CA root certificates installed by the OS (although we have seen instances in which these got removed rather than updated). For further information see <http://curl.haxx.se/docs/sslcerts.html>.

This is an issue for `method = "libcurl"` on Windows, where the OS does not provide a suitable CA certificate bundle, so by default on Windows certificates are not verified. To turn verification on, set environment variable `CURL_CA_BUNDLE` to the path to a certificate bundle file, usually named `'ca-bundle.crt'` or `'curl-ca-bundle.crt'`. (This is normally done for a binary installation of R, which installs `'R_HOME/etc/curl-ca-bundle.crt'` and sets `CURL_CA_BUNDLE` to point to it if that environment variable is not already set.) For an updated certificate bundle, see <http://curl.haxx.se/docs/sslcerts.html>. Currently one can download a copy from <https://raw.githubusercontent.com/bagder/ca-bundle/master/ca-bundle.crt> and set `CURL_CA_BUNDLE` to the full path to the downloaded file.

Note that the root certificates used by R may or may not be the same as used in a browser, and indeed different browsers may use different certificate bundles (there is typically a build option to choose either their own or the system ones).

### FTP sites

`'ftp:'` URLs are accessed using the FTP protocol which has a number of variants. One distinction is between `'active'` and `'(extended) passive'` modes: which is used is chosen by the client. The `"internal"` and `"libcurl"` method use passive mode, and that is almost universally used by browsers. Prior to R 3.2.3 the `"wininet"` method used active mode: since it first tries passive and then active.

### Note

Files of more than 2GB are supported on 64-bit builds of R; they may be truncated on some 32-bit builds.

Method `"wget"` is mainly for historical compatibility, but it and `"curl"` can be used for URLs (e.g., `'https://'` URLs or those that use cookies or redirection) which the internal method does not support and where the `"libcurl"` method is not available.

Method `"wget"` can be used with proxy firewalls which require user/password authentication if proper values are stored in the configuration file for `wget`.

`wget` (<http://www.gnu.org/software/wget/>) is commonly installed on Unix-alikes (but not OS X). Windows binaries are available from Cygwin, gnuwin32 and elsewhere.

`curl` (<http://curl.haxx.se/>) is installed on OS X and commonly on Unix-alikes. Windows binaries are available at that URL.

## Description

These functions can be used to automatically compare the version numbers of installed packages with the newest available version on the repositories and update outdated packages on the fly.

## Usage

```
download.packages(pkgs, destdir, available = NULL,
                  repos = getOption("repos"),
                  contriburl = contrib.url(repos, type),
                  method, type = getOption("pkgType"), ...)
```

## Arguments

|            |                                                                                                                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgs       | character vector of the names of packages whose latest available versions should be downloaded from the repositories.                                                                                      |
| destdir    | directory where downloaded packages are to be stored.                                                                                                                                                      |
| available  | an object as returned by <a href="#">available.packages</a> listing packages available at the repositories, or NULL which makes an internal call to <a href="#">available.packages</a> .                   |
| repos      | character vector, the base URL(s) of the repositories to use, i.e., the URL of the CRAN master such as "https://cran.r-project.org" or its Statlib mirror, "http://lib.stat.cmu.edu/R/CRAN".               |
| contriburl | URL(s) of the contrib sections of the repositories. Use this argument only if your repository mirror is incomplete, e.g., because you burned only the 'contrib' section on a CD. Overrides argument repos. |
| method     | Download method, see <a href="#">download.file</a> .                                                                                                                                                       |
| type       | character string, indicate which type of packages: see <a href="#">install.packages</a> .                                                                                                                  |
| ...        | additional arguments to be passed to <a href="#">download.file</a> .                                                                                                                                       |

## Details

`download.packages` takes a list of package names and a destination directory, downloads the newest versions and saves them in `destdir`. If the list of available packages is not given as argument, it is obtained from repositories. If a repository is local, i.e. the URL starts with "file:", then the packages are not downloaded but used directly. Both "file:" and "file:///" are allowed as prefixes to a file path. Use the latter only for URLs: see [url](#) for their interpretation. (Other forms of 'file://' URLs are not supported.)

## Value

A two-column matrix of names and destination file names of those packages successfully downloaded. If packages are not available or there is a problem with the download, suitable warnings are given.

**See Also**

edit

*Invoke a Text Editor*

---

**Description**

Invoke a text editor on an R object.

**Usage**

```
## Default S3 method:
edit(name = NULL, file = "", title = NULL,
      editor = getOption("editor"), ...)

vi(name = NULL, file = "")
emacs(name = NULL, file = "")
pico(name = NULL, file = "")
xemacs(name = NULL, file = "")
xedit(name = NULL, file = "")
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name   | a named object that you want to edit. If name is missing then the file specified by file is opened for editing.                                                                                                                                                                                                                                                                                                                                                                                                           |
| file   | a string naming the file to write the edited version to.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| title  | a display name for the object being edited.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| editor | usually a string naming the text editor you want to use. On Unix the default is set from the environment variables EDITOR or VISUAL if either is set, otherwise vi is used. On Windows it defaults to "internal", the script editor. On the OS X GUI the argument is ignored and the document editor is always used.<br><br>editor can also be a function, in which case it is called with the arguments name, file, and title. Note that such a function will need to independently implement all desired functionality. |
| ...    | further arguments to be passed to or from methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Details

edit invokes the text editor specified by editor with the object name to be edited. It is a generic function, currently with a default method and one for data frames and matrices.

data.entry can be used to edit data, and is used by edit to edit matrices and data frames on systems for which data.entry is available.

It is important to realize that edit does not change the object called name. Instead, a copy of name is made and it is that copy which is changed. Should you want the changes to apply to the object name you must assign the result of edit to name. (Try [fix](#) if you want to make permanent changes to an object.)

In the form edit(name), edit deparses name into a temporary file and invokes the editor editor on this file. Quitting from the editor causes file to be parsed and that value returned. Should an error occur in parsing, possibly due to incorrect syntax, no value is returned. Calling edit(), with no arguments, will result in the temporary file being reopened for further editing.

Note that deparsing is not perfect, and the object recreated after editing can differ in subtle ways from that deparsed: see [dput](#) and [.deparseOpts](#). (The deparse options used are the same as the defaults for dump.) Editing a function will preserve its environment. See [edit.data.frame](#) for further changes that can occur when editing a data frame or matrix.

Currently only the internal editor in Windows makes use of the title option; it displays the given name in the window header.

## Note

The functions vi, emacs, pico, xemacs, xedit rely on the corresponding editor being available and being on the path. This is system-dependent.

## Examples

```
## Not run:
# use xedit on the function mean and assign the changes
mean <- edit(mean, editor = "xedit")

# use vi on mean and write the result to file mean.out
vi(mean, file = "mean.out")

## End(Not run)
```

---

edit.data.frame

---

*Edit Data Frames and Matrices*

---

## Description

Use data editor on data frame or matrix contents.

**Usage**

```
## S3 method for class 'data.frame'
edit(name, factor.mode = c("character", "numeric"),
      edit.row.names = any(row.names(name) != 1:nrow(name)), ...)

## S3 method for class 'matrix'
edit(name, edit.row.names = !is.null(dn[[1]]), ...)
```

**Arguments**

|                             |                                                                                                                                                         |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>           | A data frame or (numeric, logical or character) matrix.                                                                                                 |
| <code>factor.mode</code>    | How to handle factors (as integers or using character levels) in a data frame. Can be abbreviated.                                                      |
| <code>edit.row.names</code> | logical. Show the row names (if they exist) be displayed as a separate editable column? It is an error to ask for this on a matrix with NULL row names. |
| <code>...</code>            | further arguments passed to or from other methods.                                                                                                      |

**Details**

At present, this only works on simple data frames containing numeric, logical or character vectors and factors, and numeric, logical or character matrices. Any other mode of matrix will give an error, and a warning is given when the matrix has a class (which will be discarded).

Data frame columns are coerced on input to *character* unless numeric (in the sense of `is.numeric`), logical or factor. A warning is given when classes are discarded. Special characters (tabs, non-printing ASCII, etc.) will be displayed as escape sequences.

Factors columns are represented in the spreadsheet as either numeric vectors (which are more suitable for data entry) or character vectors (better for browsing). After editing, vectors are padded with NA to have the same length and factor attributes are restored. The set of factor levels can not be changed by editing in numeric mode; invalid levels are changed to NA and a warning is issued. If new factor levels are introduced in character mode, they are added at the end of the list of levels in the order in which they encountered.

It is possible to use the data-editor's facilities to select the mode of columns to swap between numerical and factor columns in a data frame. Changing any column in a numerical matrix to character will cause the result to be coerced to a character matrix. Changing the mode of logical columns is not supported.

For a data frame, the row names will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged, and from the edited output if `edit.row.names = TRUE` and there are no duplicates. (If the `row.names` column is incomplete, it is extended by entries like `row223`.) In all other cases the row names are replaced by `seq(length = nrow)`.

For a matrix, `colnames` will be added (of the form `col17`) if needed. The `rownames` will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged (otherwise NULL), and from the edited output if `edit.row.names = TRUE`. (If the `row.names` column is incomplete, it is extended by entries like `row223`.)

Editing a matrix or data frame will lose all attributes apart from the row and column names.

**Value**

The edited data frame or matrix.

**Note**

`fix(dataframe)` works for in-place editing by calling this function.

If the data editor is not available, a dump of the object is presented for editing using the default method of `edit`.

At present the data editor is limited to 65535 rows.

example

*Run an Examples Section from the Online Help*

---

**Description**

Run all the R code from the **Examples** part of R's online help topic with possible exceptions `dontrun`, `dontshow`, and `donttest`, see 'Details' below.

**Usage**

```
example(topic, package = NULL, lib.loc = NULL,
        character.only = FALSE, give.lines = FALSE, local = FALSE,
        echo = TRUE, verbose = getOption("verbose"),
        setRNG = FALSE, ask = getOption("example.ask"),
        prompt.prefix = abbreviate(topic, 6),
        run.dontrun = FALSE, run.donttest = interactive())
```

**Arguments**

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>topic</code>          | name or literal character string: the online <a href="#">help</a> topic the examples of which should be run.                                                                                                                                                                                                                                                                                                                  |
| <code>package</code>        | a character vector giving the package names to look into for the topic, or <code>NULL</code> (the default), when all packages on the <a href="#">search</a> path are used.                                                                                                                                                                                                                                                    |
| <code>lib.loc</code>        | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.                                                                                                                                                                              |
| <code>character.only</code> | a logical indicating whether <code>topic</code> can be assumed to be a character string.                                                                                                                                                                                                                                                                                                                                      |
| <code>give.lines</code>     | logical: if true, the <i>lines</i> of the example source code are returned as a character vector.                                                                                                                                                                                                                                                                                                                             |
| <code>local</code>          | logical: if <code>TRUE</code> evaluate locally, if <code>FALSE</code> evaluate in the workspace.                                                                                                                                                                                                                                                                                                                              |
| <code>echo</code>           | logical; if <code>TRUE</code> , show the R input when sourcing.                                                                                                                                                                                                                                                                                                                                                               |
| <code>verbose</code>        | logical; if <code>TRUE</code> , show even more when running example code.                                                                                                                                                                                                                                                                                                                                                     |
| <code>setRNG</code>         | logical or expression; if not <code>FALSE</code> , the random number generator state is saved, then initialized to a specified state, the example is run and the (saved) state is restored. <code>setRNG = TRUE</code> sets the same state as R CMD <a href="#">check</a> does for running a package's examples. This is currently equivalent to <code>setRNG = {RNGkind("default", "default"); set.seed(1)}</code> .         |
| <code>ask</code>            | logical (or "default") indicating if <a href="#">devAskNewPage</a> ( <code>ask = TRUE</code> ) should be called before graphical output happens from the example code. The value "default" (the factory-fresh default) means to ask if <code>echo == TRUE</code> and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the example code. |
| <code>prompt.prefix</code>  | character; prefixes the prompt to be used if <code>echo = TRUE</code> .                                                                                                                                                                                                                                                                                                                                                       |
| <code>run.dontrun</code>    | logical indicating that <code>\dontrun</code> should be ignored.                                                                                                                                                                                                                                                                                                                                                              |
| <code>run.donttest</code>   | logical indicating that <code>\donttest</code> should be ignored.                                                                                                                                                                                                                                                                                                                                                             |

**Details**

If `lib.loc` is not specified, the packages are searched for amongst those already loaded, then in the libraries given by `.libPaths()`. If `lib.loc` is specified, packages are searched for only in the specified libraries, even if they are already loaded from another library. The search stops at the first package found that has help on the topic.

An attempt is made to load the package before running the examples, but this will not replace a package loaded from another location.

If `local = TRUE` objects are not created in the workspace and so not available for examination after example completes: on the other hand they cannot overwrite objects of the same name in the workspace.

As detailed in the manual *Writing R Extensions*, the author of the help page can markup parts of the examples for exception rules

`dontrun` encloses code that should not be run.

`dontshow` encloses code that is invisible on help pages, but will be run both by the package checking tools, and the `example()` function. This was previously `testonly`, and that form is still accepted.

`donttest` encloses code that typically should be run, but not during package checking. The default `run.donttest = interactive()` leads `example()` use in other help page examples to skip `\donttest` sections appropriately.

## Value

The value of the last evaluated expression, unless `give.lines` is true, where a [character](#) vector is returned.

## Examples

```
example(InsectSprays)
## force use of the standard package 'stats':
example("smooth", package = "stats", lib.loc = .Library)

## set RNG *before* example as when R CMD check is run:

r1 <- example(quantile, setRNG = TRUE)
x1 <- rnorm(1)
u <- runif(1)
## identical random numbers
r2 <- example(quantile, setRNG = TRUE)
x2 <- rnorm(1)
stopifnot(identical(r1, r2))
## but x1 and x2 differ since the RNG state from before example()
## differs and is restored!
x1; x2

## Exploring examples code:
## How large are the examples of "lm..()" functions?
lmex <- sapply(apropos("^lm", mode = "function"),
              example, character.only = TRUE, give.lines = TRUE)
sapply(lmex, length)
```

---

file.edit*Edit One or More Files*

---

**Description**

Edit one or more files in a text editor.

**Usage**

```
file.edit(..., title = file, editor = getOption("editor"),
          fileEncoding = "")
```

**Arguments**

|              |                                                                                                                                                      |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| ...          | one or more character vectors containing the names of the files to be displayed. These will be tilde-expanded: see <a href="#">path.expand</a> .     |
| title        | the title to use in the editor; defaults to the filename.                                                                                            |
| editor       | the text editor to be used. See ‘Details’.                                                                                                           |
| fileEncoding | the encoding to assume for the file: the default is to assume the native encoding. See the ‘Encoding’ section of the help for <a href="#">file</a> . |

**Details**

The behaviour of this function is very system dependent. Currently files can be opened only one at a time on Unix; on Windows, the internal editor allows multiple files to be opened, but has a limit of 50 simultaneous edit windows.

The title argument is used for the window caption in Windows, and is currently ignored on other platforms.

Any error in re-encoding the files to the native encoding will cause the function to fail.

The default for editor is system-dependent. On Windows it defaults to "internal", the script editor, and in the OS X GUI the document editor is used whatever the value of editor. On Unix the default is set from the environment variables EDITOR or VISUAL if either is set, otherwise vi is used.

file\_test*Shell-style Tests on Files*

---

## Description

Utility for shell-style file tests.

## Usage

```
file_test(op, x, y)
```

## Arguments

|      |                                                                                                                                                                                                                                                                                                                                                                                                        |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| op   | a character string specifying the test to be performed. Unary tests (only x is used) are "-f" (existence and not being a directory), "-d" (existence and directory) and "-x" (executable as a file or searchable as a directory). Binary tests are "-nt" (strictly newer than, using the modification dates) and "-ot" (strictly older than): in both cases the test is false unless both files exist. |
| x, y | character vectors giving file paths.                                                                                                                                                                                                                                                                                                                                                                   |

## Details

'Existence' here means being on the file system and accessible by the stat system call (or a 64-bit extension) – on a Unix-alike this requires execute permission on all of the directories in the path that leads to the file, but no permissions on the file itself.

For the meaning of "-x" on Windows see [file.access](#).

## See Also

[file.exists](#) which only tests for existence (test -e on some systems) but not for not being a directory.

[file.path](#), [file.info](#)

## Examples

```
dir <- file.path(R.home(), "library", "stats")
file_test("-d", dir)
file_test("-nt", file.path(dir, "R"), file.path(dir, "demo"))
```

---

|             |                                                                               |
|-------------|-------------------------------------------------------------------------------|
| findLineNum | <i>Find the Location of a Line of Source Code, or Set a Breakpoint There.</i> |
|-------------|-------------------------------------------------------------------------------|

---

### Description

These functions locate objects containing particular lines of source code, using the information saved when the code was parsed with `keep.source = TRUE`.

### Usage

```
findLineNum(srcfile, line, nameonly = TRUE,
            envir = parent.frame(), lastenv)

setBreakpoint(srcfile, line, nameonly = TRUE,
              envir = parent.frame(), lastenv, verbose = TRUE,
              tracer, print = FALSE, clear = FALSE, ...)
```

### Arguments

|          |                                                                                                                           |
|----------|---------------------------------------------------------------------------------------------------------------------------|
| srcfile  | The name of the file containing the source code.                                                                          |
| line     | The line number within the file. See Details for an alternate way to specify this.                                        |
| nameonly | If TRUE (the default), we require only a match to <code>basename(srcfile)</code> , not to the full path.                  |
| envir    | Where do we start looking for function objects?                                                                           |
| lastenv  | Where do we stop? See the Details.                                                                                        |
| verbose  | Should we print information on where breakpoints were set?                                                                |
| tracer   | An optional tracer function to pass to <a href="#">trace</a> . By default, a call to <a href="#">browser</a> is inserted. |
| print    | The print argument to pass to <a href="#">trace</a> .                                                                     |
| clear    | If TRUE, call <a href="#">untrace</a> rather than <a href="#">trace</a> .                                                 |
| ...      | Additional arguments to pass to <a href="#">trace</a> .                                                                   |

### Details

The `findLineNum` function searches through all objects in environment `envir`, its parent, grandparent, etc., all the way back to `lastenv`.

`lastenv` defaults to the global environment if `envir` is not specified, and to the root environment [emptyenv\(\)](#) if `envir` is specified. (The first default tends to be quite fast, and will usually find all user code other than S4 methods; the second one is quite slow, as it will typically search all attached system libraries.)

For convenience, `envir` may be specified indirectly: if it is not an environment, it will be replaced with `environment(envir)`.

`setBreakpoint` is a simple wrapper function for [trace](#) and [untrace](#). It will set or clear breakpoints at the locations found by `findLineNum`.

The `srcfile` is normally a filename entered as a character string, but it may be a "`srcfile`" object, or it may include a suffix like "`filename.R#nn`", in which case the number `nn` will be used as a default value for `line`.

As described in the description of the `where` argument on the man page for `trace`, the R package system uses a complicated scheme that may include more than one copy of a function in a package. The user will typically see the public one on the search path, while code in the package will see a private one in the package namespace. If you set `envir` to the environment of a function in the package, by default `findLineNum` will find both versions, and `setBreakpoint` will set the breakpoint in both. (This can be controlled using `lastenv`; e.g., `envir = environment(foo)`, `lastenv = globalenv()` will find only the private copy, as the search is stopped before seeing the public copy.)

S version 4 methods are also somewhat tricky to find. They are stored with the generic function, which may be in the **base** or other package, so it is usually necessary to have `lastenv = emptyenv()` in order to find them. In some cases transformations are done by R when storing them and `findLineNum` may not be able to find the original code. Many special cases, e.g. methods on primitive generics, are not yet supported.

## Value

`findLineNum` returns a list of objects containing location information. A print method is defined for them.

`setBreakpoint` has no useful return value; it is called for the side effect of calling `trace` or `untrace`.

## Examples

```
## Not run:
# Find what function was defined in the file mysource.R at line 100:
findLineNum("mysource.R#100")

# Set a breakpoint in both copies of that function, assuming one is in the
# same namespace as myfunction and the other is on the search path
setBreakpoint("mysource.R#100", envir = myfunction)

## End(Not run)
```

---

fix

---

*Fix an Object*

---

## Description

fix invokes [edit](#) on x and then assigns the new (edited) version of x in the user's workspace.

## Usage

```
fix(x, ...)
```

## Arguments

|     |                                                           |
|-----|-----------------------------------------------------------|
| x   | the name of an R object, as a name or a character string. |
| ... | arguments to pass to editor: see <a href="#">edit</a> .   |

## Details

The name supplied as x need not exist as an R object, in which case a function with no arguments and an empty body is supplied for editing.

Editing an R object may change it in ways other than are obvious: see the comment under [edit](#). See [edit.data.frame](#) for changes that can occur when editing a data frame or matrix.

## Examples

```
## Not run:
## Assume 'my.fun' is a user defined function :
fix(my.fun)
## now my.fun is changed
## Also,
fix(my.data.frame) # calls up data editor
fix(my.data.frame, factor.mode="char") # use of ...

## End(Not run)
```

---

flush.console

---

*Flush Output to A Console*

---

### Description

This does nothing except on console-based versions of R. On the OS X and Windows GUIs, it ensures that the display of output in the console is current, even if output buffering is on.

### Usage

```
flush.console()
```

---

format

---

*Format Unordered and Ordered Lists*

---

### Description

Format unordered (itemize) and ordered (enumerate) lists.

### Usage

```
formatUL(x, label = "*", offset = 0,
         width = 0.9 * getOption("width"))
formatOL(x, type = "arabic", offset = 0, start = 1,
         width = 0.9 * getOption("width"))
```

### Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | a character vector of list items.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| label  | a character string used for labelling the items.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| offset | a non-negative integer giving the offset (indentation) of the list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| width  | a positive integer giving the target column for wrapping lines in the output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| type   | a character string specifying the ‘type’ of the labels in the ordered list. If "arabic" (default), arabic numerals are used. For "Alph" or "alph", single upper or lower case letters are employed (in this case, the number of the last item must not exceed 26. Finally, for "Roman" or "roman", the labels are given as upper or lower case roman numerals (with the number of the last item maximally 3899). type can be given as a unique abbreviation of the above, or as one of the HTML style tokens "1" (arabic), "A"/"a" (alphabetic), or "I"/"i" (roman), respectively. |
| start  | a positive integer specifying the starting number of the first item in an ordered list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Value**

A character vector with the formatted entries.

**See Also**

[formatDL](#) for formatting description lists.

**Examples**

```
## A simpler recipe.
x <- c("Mix dry ingredients thoroughly.",
      "Pour in wet ingredients.",
      "Mix for 10 minutes.",
      "Bake for one hour at 300 degrees.")
## Format and output as an unordered list.
writeLines(formatUL(x))
## Format and output as an ordered list.
writeLines(formatOL(x))
## Ordered list using lower case roman numerals.
writeLines(formatOL(x, type = "i"))
## Ordered list using upper case letters and some offset.
writeLines(formatOL(x, type = "A", offset = 5))
```

---

getAnywhere

*Retrieve an R Object, Including from a Namespace*

---

**Description**

These functions locate all objects with name matching their argument, whether visible on the search path, registered as an S3 method or in a namespace but not exported. `getAnywhere()` returns the objects and `argsAnywhere()` returns the arguments of any objects that are functions.

**Usage**

```
getAnywhere(x)
argsAnywhere(x)
```

**Arguments**

`x` a character string or name.

**Details**

These functions look at all loaded namespaces, whether or not they are associated with a package on the search list.

They do not search literally “anywhere”: for example, local evaluation frames and namespaces that are not loaded will not be searched.

Where functions are found as registered S3 methods, an attempt is made to find which namespace registered them. This may not be correct, especially if namespaces have been unloaded.

**Value**

For `getAnywhere()` an object of class "getAnywhere". This is a list with components

|                      |                                                              |
|----------------------|--------------------------------------------------------------|
| <code>name</code>    | the name searched for                                        |
| <code>objs</code>    | a list of objects found                                      |
| <code>where</code>   | a character vector explaining where the object(s) were found |
| <code>visible</code> | logical: is the object visible                               |
| <code>dups</code>    | logical: is the object identical to one earlier in the list. |

In computing whether objects are identical, their environments are ignored.

Normally the structure will be hidden by the `print` method. There is a `[` method to extract one or more of the objects found.

For `argsAnywhere()` one or more argument lists as returned by [args](#).

**See Also**

[getS3method](#) to find the method which would be used: this might not be the one of those returned by `getAnywhere` since it might have come from a namespace which was unloaded or be registered under another name.

[get](#), [getFromNamespace](#), [args](#)

**Examples**

```
getAnywhere("format.dist")
getAnywhere("simpleLoess") # not exported from stats
argsAnywhere(format.dist)
```

---

|                               |                                                    |
|-------------------------------|----------------------------------------------------|
| <code>getFromNamespace</code> | <i>Utility functions for Developing Namespaces</i> |
|-------------------------------|----------------------------------------------------|

---

**Description**

Utility functions to access and replace the non-exported functions in a namespace, for use in developing packages with namespaces.

They should not be used in production code (except perhaps `assignInMyNamespace`, but see the 'Note').

**Usage**

```
getFromNamespace(x, ns, pos = -1, envir = as.environment(pos))

assignInNamespace(x, value, ns, pos = -1,
                  envir = as.environment(pos))

assignInMyNamespace(x, value)

fixInNamespace(x, ns, pos = -1, envir = as.environment(pos), ...)
```

### Arguments

|       |                                                             |
|-------|-------------------------------------------------------------|
| x     | an object name (given as a character string).               |
| value | an R object.                                                |
| ns    | a namespace, or character string giving the namespace.      |
| pos   | where to look for the object: see <a href="#">get</a> .     |
| envir | an alternative way to specify an environment to look in.    |
| ...   | arguments to pass to the editor: see <a href="#">edit</a> . |

### Details

`assignInMyNamespace` is intended to be called from functions within a package, and chooses the namespace as the environment of the function calling it.

The namespace can be specified in several ways. Using, for example, `ns = "stats"` is the most direct, but a loaded package can be specified via any of the methods used for [get](#): `ns` can also be the environment printed as `<namespace:foo>`.

`getFromNamespace` is similar to (but predates) the `:::` operator: it is more flexible in how the namespace is specified.

`fixInNamespace` invokes [edit](#) on the object named `x` and assigns the revised object in place of the original object. For compatibility with `fix`, `x` can be unquoted.

### Value

`getFromNamespace` returns the object found (or gives an error).

`assignInNamespace`, `assignInMyNamespace` and `fixInNamespace` are invoked for their side effect of changing the object in the namespace.

### Warning

`assignInNamespace` should not be used in final code, and will in future throw an error if called from a package. Already certain uses are disallowed.

### Note

`assignInNamespace`, `assignInMyNamespace` and `fixInNamespace` change the copy in the namespace, but not any copies already exported from the namespace, in particular an object of that name in the package (if already attached) and any copies already imported into other namespaces. They are really intended to be used *only* for objects which are not exported from the namespace. They do attempt to alter a copy registered as an S3 method if one is found.

They can only be used to change the values of objects in the namespace, not to create new objects.

### See Also

## Examples

```
getFromNamespace("findGeneric", "utils")
## Not run:
fixInNamespace("predict.ppr", "stats")
stats::predict.ppr
getS3method("predict", "ppr")
## alternatively
fixInNamespace("predict.ppr", pos = 3)
fixInNamespace("predict.ppr", pos = "package:stats")

## End(Not run)
```

---

|              |                                                    |
|--------------|----------------------------------------------------|
| getParseData | <i>Get detailed parse information from object.</i> |
|--------------|----------------------------------------------------|

---

## Description

If the "keep.source" option is TRUE, R's parser will attach detailed information on the object it has parsed. These functions retrieve that information.

## Usage

```
getParseData(x, includeText = NA)
getParseText(parseData, id)
```

## Arguments

|             |                                                                                                                     |
|-------------|---------------------------------------------------------------------------------------------------------------------|
| x           | an expression returned from <a href="#">parse</a> , or a function or other object with source reference information |
| includeText | logical; whether to include the text of parsed items in the result                                                  |
| parseData   | a data frame returned from <code>getParseData</code>                                                                |
| id          | a vector of item identifiers whose text is to be retrieved                                                          |

## Details

In version 3.0.0, the R parser was modified to include code written by Romain Francois in his **parser** package. This constructs a detailed table of information about every token and higher level construct in parsed code. This table is stored in the [srcfile](#) record associated with source references in the parsed code, and retrieved by the `getParseData` function.

## Value

For `getParseData`:

If parse data is not present, NULL. Otherwise a data frame is returned, containing the following columns:

|       |                                                                                                                                                                   |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| line1 | integer. The line number where the item starts. This is the parsed line number called "parse" in <a href="#">getSrcLocation</a> , which ignores #line directives. |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|          |                                                                                                                                                                                                                                                                                                                                      |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| col1     | integer. The column number where the item starts. The first character is column 1. This corresponds to "column" in <a href="#">getSrcLocation</a> .                                                                                                                                                                                  |
| line2    | integer. The line number where the item ends.                                                                                                                                                                                                                                                                                        |
| col2     | integer. The column number where the item ends.                                                                                                                                                                                                                                                                                      |
| id       | integer. An identifier associated with this item.                                                                                                                                                                                                                                                                                    |
| parent   | integer. The id of the parent of this item.                                                                                                                                                                                                                                                                                          |
| token    | character string. The type of the token.                                                                                                                                                                                                                                                                                             |
| terminal | logical. Whether the token is "terminal", i.e. a leaf in the parse tree.                                                                                                                                                                                                                                                             |
| text     | character string. If includeText is TRUE, the text of all tokens; if it is NA (the default), the text of terminal tokens. If includeText == FALSE, this column is not included. Very long strings (with source of 1000 characters or more) will not be stored; a message giving their length and delimiter will be included instead. |

The rownames of the data frame will be equal to the id values, and the data frame will have a "srcfile" attribute containing the [srcfile](#) record which was used. The rows will be ordered by starting position within the source file, with parent items occurring before their children.

For getParseText:

A character vector of the same length as id containing the associated text items. If they are not included in parseData, they will be retrieved from the original file.

## Note

There are a number of differences in the results returned by getParseData relative to those in the original **parser** code:

- Fewer columns are kept.
- The internal token number is not returned.
- col1 starts counting at 1, not 0.
- The id values are not attached to the elements of the parse tree, they are only retained in the table returned by getParseData.
- #line directives are identified, but other comment markup (e.g., **roxygen** comments) are not.

**Examples**

```
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

d <- getParseData(fn)
if (!is.null(d)) {
  plus <- which(d$token == "'+'")
  sum <- d$parent[plus]
  print(d[as.character(sum),])
  print(getParseText(d, sum))
}
```

getS3method

*Get An S3 Method***Description**

Get a method for an S3 generic, possibly from a namespace or the generic's registry.

**Usage**

```
getS3method(f, class, optional = FALSE)
```

**Arguments**

|          |                                                                     |
|----------|---------------------------------------------------------------------|
| f        | character: name of the generic.                                     |
| class    | character: name of the class.                                       |
| optional | logical: should failure to find the generic or a method be allowed? |

**Details**

S3 methods may be hidden in namespaces, and will not then be found by [get](#): this function can retrieve such functions, primarily for debugging purposes.

Further, S3 methods can be registered on the generic when a namespace is loaded, and the registered method will be used if none is visible (using namespace scoping rules).

It is possible that which S3 method will be used may depend on where the generic f is called from: getS3method returns the method found if f were called from the same environment.

**Value**

The function found, or NULL if no function is found and optional = TRUE.

## Examples

```
require(stats)
exists("predict.ppr") # false
getS3method("predict", "ppr")
```

---

**glob2rx***Change Wildcard or Globbing Pattern into Regular Expression*

---

## Description

Change *wildcard* aka *globbing* patterns into the corresponding regular expressions ([regexp](#)).

## Usage

```
glob2rx(pattern, trim.head = FALSE, trim.tail = TRUE)
```

## Arguments

|                        |                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------|
| <code>pattern</code>   | character vector                                                                        |
| <code>trim.head</code> | logical specifying if leading " <code>^.*</code> " should be trimmed from the result.   |
| <code>trim.tail</code> | logical specifying if trailing " <code>.*\$</code> " should be trimmed from the result. |

## Details

This takes a wildcard as used by most shells and returns an equivalent regular expression. `?` is mapped to `.` (match a single character), `*` to `.*` (match any string, including an empty one), and the pattern is anchored (it must start at the beginning and end at the end). Optionally, the resulting regexp is simplified.

Note that now even `(`, `[` and `{` can be used in pattern, but `glob2rx()` may not work correctly with arbitrary characters in pattern.

## Value

A character vector of the same length as the input `pattern` where each wildcard is translated to the corresponding regular expression.

## Author(s)

|                 |                                                |
|-----------------|------------------------------------------------|
| globalVariables | <i>Declarations Used in Checking a Package</i> |
|-----------------|------------------------------------------------|

---

Description

For `globalVariables`, the names supplied are of functions or other objects that should be regarded as defined globally when the check tool is applied to this package. The call to `globalVariables` will be included in the package’s source. Repeated calls in the same package accumulate the names of the global variables.

Typical examples are the fields and methods in reference classes, which appear to be global objects to codetools. (This case is handled automatically by `setRefClass()` and friends, using the supplied field and method names.)

For `suppressForeignCheck`, the names supplied are of variables used as `.NAME` in foreign function calls which should not be checked by `checkFF(registration = TRUE)`. Without this declaration, expressions other than simple character strings are assumed to evaluate to registered native symbol objects. The type of call (`.Call`, `.External`, etc.) and argument counts will be checked. With this declaration, checks on those names will usually be suppressed. (If the code uses an expression that should only be evaluated at runtime, the message can be suppressed by wrapping it in a `dontCheck` function call, or by saving it to a local variable, and suppressing messages about that variable. See the example below.)

Usage

```
globalVariables(names, package, add = TRUE)
suppressForeignCheck(names, package, add = TRUE)
```

Arguments

|         |                                                                                                                                                                                                                                                                                                                     |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| names   | The character vector of object names. If omitted, the current list of global variables declared in the package will be returned, unchanged.                                                                                                                                                                         |
| package | The relevant package, usually the character string name of the package but optionally its corresponding namespace environment.<br>When the call to <code>globalVariables</code> or <code>suppressForeignCheck</code> comes in the package’s source file, the argument is normally omitted, as in the example below. |
| add     | Should the contents of names be added to the current global variables or replace it?                                                                                                                                                                                                                                |

**Details**

The lists of declared global variables and native symbol objects are stored in a metadata object in the package's namespace, assuming the `globalVariables` or `suppressForeignCheck` call(s) occur as top-level calls in the package's source code.

The `check` command, as implemented in `package tools`, queries the list before checking the R source code in the package for possible problems.

`globalVariables` was introduced in R 2.15.1 and `suppressForeignCheck` was introduced in R 3.1.0 so both should be used conditionally: see the example.

**Value**

`globalVariables` returns the current list of declared global variables, possibly modified by this call.

`suppressForeignCheck` returns the current list of native symbol objects which are not to be checked.

**Note**

The global variables list really belongs to a restricted scope (a function or a group of method definitions, for example) rather than the package as a whole. However, implementing finer control would require changes in `check` and/or in `codetools`, so in this version the information is stored at the package level.

**Author(s)**

John Chambers and Duncan Murdoch

**See Also**

`dontCheck`.

**Examples**

```
## Not run:
## assume your package has some code that assigns ".obj1" and ".obj2"
## but not in a way that codetools can find.
## In the same source file (to remind you that you did it) add:
if(getRversion() >= "2.15.1") utils::globalVariables(c(".obj1", ".obj2"))

## To suppress messages about a run-time calculated native symbol,
## save it to a local variable.

## At top level, put this:
if(getRversion() >= "3.1.0") utils::suppressForeignCheck("localvariable")

## Within your function, do the call like this:
localvariable <- if (condition) entry1 else entry2
.Call(localvariable, 1, 2, 3)
```

```
## Alternatively, like this:
if(getRversion() < "3.1.0") dontCheck <- identity
.Call(dontCheck(if (condition) entry1 else entry2), 1, 2, 3)

## HOWEVER, it is much better practice to write code
## that can be checked thoroughly, e.g.
if(condition) .Call(entry1, 1, 2, 3) else .Call(entry2, 1, 2, 3)

## End(Not run)
```

---

head

*Return the First or Last Part of an Object*

---

## Description

Returns the first or last parts of a vector, matrix, table, data frame or function. Since `head()` and `tail()` are generic functions, they may also have been extended to other classes.

## Usage

```
head(x, ...)
## Default S3 method:
head(x, n = 6L, ...)
## S3 method for class 'data.frame'
head(x, n = 6L, ...)
## S3 method for class 'matrix'
head(x, n = 6L, ...)
## S3 method for class 'ftable'
head(x, n = 6L, ...)
## S3 method for class 'table'
head(x, n = 6L, ...)
## S3 method for class 'function'
head(x, n = 6L, ...)

tail(x, ...)
## Default S3 method:
tail(x, n = 6L, ...)
## S3 method for class 'data.frame'
tail(x, n = 6L, ...)
## S3 method for class 'matrix'
tail(x, n = 6L, addrownums = TRUE, ...)
## S3 method for class 'ftable'
tail(x, n = 6L, addrownums = FALSE, ...)
## S3 method for class 'table'
tail(x, n = 6L, addrownums = TRUE, ...)
## S3 method for class 'function'
tail(x, n = 6L, ...)
```

**Arguments**

|            |                                                                                                                                                                                                                                          |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x          | an object                                                                                                                                                                                                                                |
| n          | a single integer. If positive, size for the resulting object: number of elements for a vector (including lists), rows for a matrix or data frame or lines for a function. If negative, all but the n last/first number of elements of x. |
| addrownums | if there are no row names, create them from the row numbers.                                                                                                                                                                             |
| ...        | arguments to be passed to or from other methods.                                                                                                                                                                                         |

**Details**

For matrices, 2-dim tables and data frames, `head()` (`tail()`) returns the first (last) `n` rows when `n > 0` or all but the last (first) `n` rows when `n < 0`. `head.matrix()` and `tail.matrix()` are exported. For functions, the lines of the deparsed function are returned as character strings.

If a matrix has no row names, then `tail()` will add row names of the form "[n,]" to the result, so that it looks similar to the last lines of `x` when printed. Setting `addrownums = FALSE` suppresses this behaviour.

**Value**

An object (usually) like `x` but generally smaller. For `fable` objects `x`, a transformed `format(x)`.

**Author(s)**

Patrick Burns, improved and corrected by R-Core. Negative argument added by Vincent Goulet.

**Examples**

```
head(letters)
head(letters, n = -6L)

head(freeny.x, n = 10L)
head(freeny.y)

tail(letters)
tail(letters, n = -6L)

tail(freeny.x)
tail(freeny.y)

tail(library)

head(stats::fable(Titanic))
```

help

*Documentation***Description**

help is the primary interface to the help systems.

**Usage**

```
help(topic, package = NULL, lib.loc = NULL,
      verbose = getOption("verbose"),
      try.all.packages = getOption("help.try.all.packages"),
      help_type = getOption("help_type"))
```

**Arguments**

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| topic            | usually, a <a href="#">name</a> or character string specifying the topic for which help is sought. A character string (enclosed in explicit single or double quotes) is always taken as naming a topic.<br><br>If the value of topic is a length-one character vector the topic is taken to be the value of the only element. Otherwise topic must be a name or a <a href="#">reserved</a> word (if syntactically valid) or character string.<br>See ‘Details’ for what happens if this is omitted. |
| package          | a name or character vector giving the packages to look into for documentation, or NULL. By default, all packages whose namespaces are loaded are used. To avoid a name being deparsed use e.g. (pkg_ref) (see the examples).                                                                                                                                                                                                                                                                        |
| lib.loc          | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries. This is not used for HTML help (see ‘Details’).                                                                                                                                                                                                                               |
| verbose          | logical; if TRUE, the file name is reported.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| try.all.packages | logical; see Note.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| help_type        | character string: the type of help required. Possible values are "text", "html" and "pdf". Case is ignored, and partial matching is allowed.                                                                                                                                                                                                                                                                                                                                                        |

**Details**

The following types of help are available:

- Plain text help
- HTML help pages with hyperlinks to other topics, shown in a browser by [browseURL](#). (Where possible an existing browser window is re-used: the OS X GUI uses its own browser window.) If for some reason HTML help is unavailable (see [startDynamicHelp](#)), plain text help will be used instead.

- For help only, typeset as PDF – see the section on ‘Offline help’.

The ‘factory-fresh’ default is text help except from the OS X GUI, which uses HTML help displayed in its own browser window.

The rendering of text help will use directional quotes in suitable locales (UTF-8 and single-byte Windows locales): sometimes the fonts used do not support these quotes so this can be turned off by setting `options(useFancyQuotes = FALSE)`.

topic is not optional: if it is omitted R will give

- If a package is specified, (text or, in interactive use only, HTML) information on the package, including hints/links to suitable help topics.
- If `lib.loc` only is specified, a (text) list of available packages.
- Help on help itself if none of the first three arguments is specified.

Some topics need to be quoted (by `backticks`) or given as a character string. These include those which cannot syntactically appear on their own such as unary and binary operators, function and control-flow `reserved` words (including `if`, `else`, `for`, `in`, `repeat`, `while`, `break` and `next`). The other reserved words can be used as if they were names, for example `TRUE`, `NA` and `Inf`.

If multiple help files matching `topic` are found, in interactive use a menu is presented for the user to choose one: in batch use the first on the search path is used. (For HTML help the menu will be an HTML page, otherwise a graphical menu if possible if `getOption("menu.graphics")` is true, the default.)

Note that HTML help does not make use of `lib.loc`: it will always look first in the loaded packages and then along `.libPaths()`.

## Offline help

Typeset documentation is produced by running the LaTeX version of the help page through `pdflatex`: this will produce a PDF file.

The appearance of the output can be customized through a file ‘`Rhelp.cfg`’ somewhere in your LaTeX search path: this will be input as a LaTeX style file after `Rd.sty`. Some `environment variables` are consulted, notably `R_PAPERSIZE` (via `getOption("papersize")`) and `R_RD4PDF` (see ‘Making manuals’ in the ‘R Installation and Administration Manual’).

If there is a function `offline_help_helper` in the workspace or further down the search path it is used to do the typesetting, otherwise the function of that name in the `utils` namespace (to which the first paragraph applies). It should accept at least two arguments, the name of the LaTeX file to be typeset and the type (which is nowadays ignored). It accepts a third argument, `texinputs`, which will give the graphics path when the help document contains figures, and will otherwise not be supplied.

## Note

Unless `lib.loc` is specified explicitly, the loaded packages are searched before those in the specified libraries. This ensures that if a library is loaded from a library not in the known library trees, then the help from the loaded library is used. If `lib.loc` is specified explicitly, the loaded packages are *not* searched.

If this search fails and argument `try.all.packages` is `TRUE` and neither `packages` nor `lib.loc` is specified, then all the packages in the known library trees are searched for help on `topic` and

a list of (any) packages where help may be found is displayed (with hyperlinks for `help_type = "html"`). **NB:** searching all packages can be slow, especially the first time (caching of files by the OS can expedite subsequent searches dramatically).

## See Also

`?` for shortcuts to help topics.

`help.search()` or `??` for finding help pages on a vague topic; `help.start()` which opens the HTML version of the R help pages; `library()` for listing available packages and the help objects they contain; `data()` for listing available data sets; `methods()`.

Use `prompt()` to get a prototype for writing help pages of your own package.

## Examples

```
help()
help(help)           # the same

help(lapply)

help("for")          # or ?"for", but quotes/backticks are needed

try({# requires working TeX installation:
  help(dgamma, help_type = "pdf")
  ## -> nicely formatted pdf -- including math formula -- for help(dgamma):
  system2(getOption("pdfviewer"), "dgamma.pdf", wait = FALSE)
})

help(package = "splines") # get help even when package is not loaded

topi <- "women"
help(topi)

try(help("bs", try.all.packages = FALSE)) # reports not found (an error)
help("bs", try.all.packages = TRUE)      # reports can be found
                                          # in package 'splines'

## For programmatic use:
topic <- "family"; pkg_ref <- "stats"
help((topic), (pkg_ref))
```

|              |                              |
|--------------|------------------------------|
| help.request | <i>Send a Post to R-help</i> |
|--------------|------------------------------|

---

### Description

Prompts the user to check they have done all that is expected of them before sending a post to the R-help mailing list, provides a template for the post with session information included and optionally sends the email (on Unix systems).

### Usage

```
help.request(subject = "",
             address = "r-help@R-project.org",
             file = "R.help.request", ...)
```

### Arguments

|         |                                                                                                                             |
|---------|-----------------------------------------------------------------------------------------------------------------------------|
| subject | subject of the email. Please do not use single quotes (') in the subject! Post separate help requests for multiple queries. |
| address | recipient's email address.                                                                                                  |
| file    | filename to use (if needed) for setting up the email.                                                                       |
| ...     | additional named arguments such as method and ccaddress to pass to <a href="#">create.post</a> .                            |

### Details

This function is not intended to replace the posting guide. Please read the guide before posting to R-help or using this function (see <https://www.r-project.org/posting-guide.html>).

The help.request function:

- asks whether the user has consulted relevant resources, stopping and opening the relevant URL if a negative response is given.
- checks whether the current version of R is being used and whether the add-on packages are up-to-date, giving the option of updating where necessary.
- asks whether the user has prepared appropriate (minimal, reproducible, self-contained, commented) example code ready to paste into the post.

Once this checklist has been completed a template post is prepared including current session information, and passed to [create.post](#).

### Value

Nothing useful.

### Author(s)

Heather Turner, based on the then current code and help page of [bug.report\(\)](#).

**See Also**

The posting guide (<https://www.r-project.org/posting-guide.html>), also `sessionInfo()` from which you may add to the help request.  
[create.post](#).

help.search

---

*Search the Help System*

---

**Description**

Allows for searching the help system for documentation matching a given character string in the (file) name, alias, title, concept or keyword entries (or any combination thereof), using either [fuzzy matching](#) or [regular expression](#) matching. Names and titles of the matched help entries are displayed nicely formatted.

Vignette names, titles and keywords and demo names and titles may also be searched.

**Usage**

```
help.search(pattern, fields = c("alias", "concept", "title"),
            apropos, keyword, whatis, ignore.case = TRUE,
            package = NULL, lib.loc = NULL,
            help.db = getOption("help.db"),
            verbose = getOption("verbose"),
            rebuild = FALSE, agrep = NULL, use_UTF8 = FALSE,
            types = getOption("help.search.types"))
??pattern
field??pattern
```

**Arguments**

|             |                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pattern     | a character string to be matched in the specified fields. If this is given, the arguments apropos, keyword, and whatis are ignored.                                                                                                                                                                                                                                                              |
| fields      | a character vector specifying the fields of the help database to be searched. The entries must be abbreviations of "name", "title", "alias", "concept", and "keyword", corresponding to the help page's (file) name, its title, the topics and concepts it provides documentation for, and the keywords it can be classified to. See below for details and how vignettes and demos are searched. |
| apropos     | a character string to be matched in the help page topics and title.                                                                                                                                                                                                                                                                                                                              |
| keyword     | a character string to be matched in the help page 'keywords'. 'Keywords' are really categories: the standard categories are listed in file 'R.home("doc")/KEYWORDS' (see also the example) and some package writers have defined their own. If keyword is specified, agrep defaults to FALSE.                                                                                                    |
| whatis      | a character string to be matched in the help page topics.                                                                                                                                                                                                                                                                                                                                        |
| ignore.case | a logical. If TRUE, case is ignored during matching; if FALSE, pattern matching is case sensitive.                                                                                                                                                                                                                                                                                               |

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package  | a character vector with the names of packages to search through, or NULL in which case <i>all</i> available packages in the library trees specified by <code>lib.loc</code> are searched.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| lib.loc  | a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| help.db  | a character string giving the file path to a previously built and saved help database, or NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| verbose  | logical; if TRUE, the search process is traced. Integer values are also accepted, with TRUE being equivalent to 2, and 1 being less verbose. On Windows a progress bar is shown during rebuilding, and on Unix a heartbeat is shown for <code>verbose = 1</code> and a package-by-package list for <code>verbose &gt;= 2</code> .                                                                                                                                                                                                                                                                                            |
| rebuild  | a logical indicating whether the help database should be rebuilt. This will be done automatically if <code>lib.loc</code> or the search path is changed, or if package is used and a value is not found.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| agrep    | if NULL (the default unless keyword is used) and the character string to be matched consists of alphanumeric characters, whitespace or a dash only, approximate (fuzzy) matching via <a href="#">agrep</a> is used unless the string has fewer than 5 characters; otherwise, it is taken to contain a <a href="#">regular expression</a> to be matched via <a href="#">grep</a> . If FALSE, approximate matching is not used. Otherwise, one can give a numeric or a list specifying the maximal distance for the approximate match, see argument <code>max.distance</code> in the documentation for <a href="#">agrep</a> . |
| use_UTF8 | logical: should results be given in UTF-8 encoding? Also changes the meaning of regexps in <a href="#">agrep</a> to be Perl regexps.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| types    | a character vector listing the types of documentation to search. The entries must be abbreviations of "vignette" "help" or "demo". Results will be presented in the order specified.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| field    | a single value of fields to search.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Details

Upon installation of a package, a pre-built help.search index is serialized as 'hsearch.rds' in the 'Meta' directory (provided the package has any help pages). Vignettes are also indexed in the 'Meta/vignette.rds' file. These files are used to create the help search database via [hsearch\\_db](#).

The arguments `apropos` and `what.is` play a role similar to the Unix commands with the same names.

Searching with `agrep = FALSE` will be several times faster than the default (once the database is built). However, approximate searches should be fast enough (around a second with 5000 packages installed).

If possible, the help database is saved in memory for use by subsequent calls in the session.

Note that currently the aliases in the matching help files are not displayed.

As with [?](#), in `??` the pattern may be prefixed with a package name followed by `::` or `:::` to limit the search to that package.

For help files, '\keyword' entries which are not among the standard keywords as listed in file 'KEYWORDS' in the R documentation directory are taken as concepts. For standard keyword entries different from 'internal', the corresponding descriptions from file 'KEYWORDS' are additionally taken as concepts. All '\concept' entries used as concepts.

Vignettes are searched as follows. The "name" and "alias" are both the base of the vignette filename, and the "concept" entries are taken from the `\VignetteKeyword` entries. Vignettes are not classified using the help system "keyword" classifications. Demos are handled similarly to vignettes, without the "concept" search.

## Value

The results are returned in a list object of class "hsearch", which has a print method for nicely formatting the results of the query. This mechanism is experimental, and may change in future versions of R.

In R.app on OS X, this will show up a browser with selectable items. On exiting this browser, the help pages for the selected items will be shown in separate help windows.

The internal format of the class is undocumented and subject to change.

## See Also

[hsearch\\_db](#) for more information on the help search database employed, and for utilities to inspect available concepts and keywords.

[help](#); [help.start](#) for starting the hypertext (currently HTML) version of R's online documentation, which offers a similar search mechanism.

[RSiteSearch](#) to access an on-line search of R resources.

[apropos](#) uses regexps and has nice examples.

## Examples

```
help.search("linear models")    # In case you forgot how to fit linear
                                # models
help.search("non-existent topic")

??utils::help # All the topics matching "help" in the utils package

help.search("print")            # All help pages with topics or title
                                # matching 'print'
help.search(apropos = "print")  # The same

help.search(keyword = "hplot")  # All help pages documenting high-level
                                # plots.
file.show(file.path(R.home("doc"), "KEYWORDS")) # show all keywords

## Help pages with documented topics starting with 'try'.
help.search("\\btry", fields = "alias")
```

## Description

Start the hypertext (currently HTML) version of R's online documentation.

## Usage

```
help.start(update = FALSE, gui = "irrelevant",  
           browser = getOption("browser"), remote = NULL)
```

## Arguments

|         |                                                                                                                                                                                                                                                                                                       |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| update  | logical: should this attempt to update the package index to reflect the currently available packages. (Not attempted if remote is non-NULL.)                                                                                                                                                          |
| gui     | just for compatibility with S-PLUS.                                                                                                                                                                                                                                                                   |
| browser | the name of the program to be used as hypertext browser. It should be in the PATH, or a full path specified. Alternatively, it can be an R function which will be called with a URL as its only argument. This option is normally unset on Windows, when the file-association mechanism will be used. |
| remote  | A character string giving a valid URL for the ' <i>R_HOME</i> ' directory on a remote location.                                                                                                                                                                                                       |

## Details

Unless remote is specified this requires the HTTP server to be available (it will be started if possible: see [startDynamicHelp](#)).

One of the links on the index page is the HTML package index, '`R.home("docs")/html/packages.html`', which can be remade by `make.packages.html()`. For local operation, the HTTP server will remake a temporary version of this list when the link is first clicked, and each time thereafter check if updating is needed (if `.libPaths` has changed or any of the directories has been changed). This can be slow, and using `update = TRUE` will ensure that the packages list is updated before launching the index page.

Argument remote can be used to point to HTML help published by another R installation: it will typically only show packages from the main library of that installation.

## See Also

[help\(\)](#) for on- and off-line help in other formats.

[browseURL](#) for how the help file is displayed.

[RSiteSearch](#) to access an on-line search of R resources.

**Examples**

```

help.start()
## Not run:
## the 'remote' arg can be tested by
help.start(remote = paste0("file://", R.home()))

## End(Not run)

```

hsearch-utils

*Help Search Utilities***Description**

Utilities for searching the help system.

**Usage**

```

hsearch_db(package = NULL, lib.loc = NULL,
            types = getOption("help.search.types"),
            verbose = getOption("verbose"),
            rebuild = FALSE, use_UTF8 = FALSE)
hsearch_db_concepts(db = hsearch_db())
hsearch_db_keywords(db = hsearch_db())

```

**Arguments**

|          |                                                                                                                                                                              |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package  | a character vector with the names of packages to search through, or NULL in which case <i>all</i> available packages in the library trees specified by lib.loc are searched. |
| lib.loc  | a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.            |
| types    | a character vector listing the types of documentation to search. See <a href="#">help.search</a> for details.                                                                |
| verbose  | a logical controlling the verbosity of building the help search database. See <a href="#">help.search</a> for details.                                                       |
| rebuild  | a logical indicating whether the help search database should be rebuilt. See <a href="#">help.search</a> for details.                                                        |
| use_UTF8 | logical: should results be given in UTF-8 encoding?                                                                                                                          |
| db       | a help search database as obtained by calls to hsearch_db().                                                                                                                 |

Details

`hsearch_db()` builds and caches the help search database for subsequent use by [help.search](#). (In fact, re-builds only when forced (`rebuild = TRUE`) or “necessary”.)

The format of the help search database is still experimental, and may change in future versions. Currently, it consists of four tables: one with base information about all documentation objects found, including their names and titles and unique ids; three more tables contain the individual aliases, concepts and keywords together with the ids of the documentation objects they belong to. Separating out the latter three tables accounts for the fact that a single documentation object may provide several of these entries, and allows for efficient searching.

See the details in [help.search](#) for how searchable entries are interpreted according to help type.

`hsearch_db_concepts()` and `hsearch_db_keywords()` extract all concepts or keywords, respectively, from a help search database, and return these in a data frame together with their total frequencies and the numbers of packages they are used in, with entries sorted in decreasing total frequency.

Examples

```
db <- hsearch_db()
## Total numbers of documentation objects, aliases, keywords and
## concepts (using the current format):
sapply(db, NROW)
## Can also be obtained from print method:
db
## 10 most frequent concepts:
head(hsearch_db_concepts(), 10)
## 10 most frequent keywords:
head(hsearch_db_keywords(), 10)
```

---

|         |                                |
|---------|--------------------------------|
| INSTALL | <i>Install Add-on Packages</i> |
|---------|--------------------------------|

---

Description

Utility for installing add-on packages.

Usage

```
R CMD INSTALL [options] [-l lib] pkgs
```

Arguments

|                      |                                                                                                                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pkgs</code>    | a space-separated list with the path names of the packages to be installed. See ‘Details’.                                                                                                           |
| <code>lib</code>     | the path name of the R library tree to install to. Also accepted in the form ‘--library=lib’. Paths including spaces should be quoted, using the conventions for the shell in use.                   |
| <code>options</code> | a space-separated list of options through which in particular the process for building the help files can be controlled. Use <code>R CMD INSTALL --help</code> for the full current list of options. |

## Details

This will stop at the first error, so if you want all the pkgs to be tried, call this via a shell loop.

If used as `R CMD INSTALL pkgs` without explicitly specifying `lib`, packages are installed into the library tree rooted at the first directory in the library path which would be used by `R` run in the current environment.

To install into the library tree `lib`, use `R CMD INSTALL -l lib pkgs`. This prepends `lib` to the library path for duration of the install, so required packages in the installation directory will be found (and used in preference to those in other libraries).

Both `lib` and the elements of `pkgs` may be absolute or relative path names of directories. `pkgs` may also contain names of package archive files: these are then extracted to a temporary directory. These are tarballs containing a single directory, optionally compressed by `gzip`, `bzip2`, `xz` or `compress`. Finally, binary package archive files (as created by `R CMD INSTALL --build`) can be supplied.

Tarballs are by default unpackaged by the internal `untar` function: if needed an external `tar` command can be specified by the environment variable `R_INSTALL_TAR`: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting `R_INSTALL_TAR` to `'tar.exe'` has been needed to overcome permissions issues on some Windows systems.)

The package sources can be cleaned up prior to installation by `'--preclean'` or after by `'--clean'`: cleaning is essential if the sources are to be used with more than one architecture or platform.

Some package sources contain a `'configure'` script that can be passed arguments or variables via the option `'--configure-args'` and `'--configure-vars'`, respectively, if necessary. The latter is useful in particular if libraries or header files needed for the package are in non-system directories. In this case, one can use the configure variables `LIBS` and `CPPFLAGS` to specify these locations (and set these via `'--configure-vars'`), see section “Configuration variables” in “R Installation and Administration” for more information. (If these are used more than once on the command line they are concatenated.) The configure mechanism can be bypassed using the option `'--no-configure'`.

If the attempt to install the package fails, leftovers are removed. If the package was already installed, the old version is restored. This happens either if a command encounters an error or if the install is interrupted from the keyboard: after cleaning up the script terminates.

For details of the locking which is done, see the section ‘Locking’ in the help for [install.packages](#).

Option `'--build'` can be used to tar up the installed package for distribution as a binary package (as used on OS X). This is done by `utils::tar` unless environment variable `R_INSTALL_TAR` is set.

By default a package is installed with static HTML help pages if and only if `R` was: use options `'--html'` and `'--no-html'` to override this.

Packages are not by default installed keeping the source formatting (see the `keep.source` argument to [source](#)): this can be enabled by the option `'--with-keep.source'` or by setting environment variable `R_KEEP_PKG_SOURCE` to `yes`.

Use `R CMD INSTALL --help` for concise usage information, including all the available options.

## Sub-architectures

An `R` installation can support more than one sub-architecture: currently this is most commonly used for 32- and 64-bit builds on Windows.

For such installations, the default behaviour is to try to install source packages for all installed sub-architectures unless the package has a configure script or a 'src/Makefile' (or 'src/Makefile.win' on Windows), when only compiled code for the sub-architecture running R CMD INSTALL is installed.

To install a source package with compiled code only for the sub-architecture used by R CMD INSTALL, use '--no-multiarch'. To install just the compiled code for another sub-architecture, use '--libs-only'.

There are two ways to install for all available sub-architectures. If the configure script is known to work for both Windows architectures, use flag '--force-biarch' (and packages can specify this via a 'Biarch' field in their DESCRIPTION files). Second, a single tarball can be installed with

```
R CMD INSTALL --merge-multiarch mypkg_version.tar.gz
```

### Note

The options do not have to precede 'pkgs' on the command line, although it will be more legible if they do. All the options are processed before any packages, and where options have conflicting effects the last one will win.

Some parts of the operation of INSTALL depend on the R temporary directory (see [tempdir](#), usually under '/tmp') having both write and execution access to the account running R. This is usually the case, but if '/tmp' has been mounted as noexec, environment variable TMPDIR may need to be set to a directory from which execution is allowed.

---

install.packages

---

*Install Packages from Repositories or Local Files*

---

### Description

Download and install packages from CRAN-like repositories or from local files.

### Usage

```
install.packages(pkgs, lib, repos = getOption("repos"),
  contriburl = contrib.url(repos, type),
  method, available = NULL, destdir = NULL,
  dependencies = NA, type = getOption("pkgType"),
  configure.args = getOption("configure.args"),
```

```

configure.vars = getOption("configure.vars"),
clean = FALSE, Ncpus = getOption("Ncpus", 1L),
verbose = getOption("verbose"),
libs_only = FALSE, INSTALL_opts, quiet = FALSE,
keep_outputs = FALSE, ...)

```

## Arguments

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pkgs</code>         | <p>character vector of the names of packages whose current versions should be downloaded from the repositories.</p> <p>If <code>repos = NULL</code>, a character vector of file paths. These can be source directories or archives or binary package archive files (as created by R CMD build --binary). (<a href="http://">http://</a> and <a href="file://">file://</a> URLs are also accepted and the files will be downloaded and installed from local copies.) On a CRAN build of R for OS X these can be <code>.tgz</code> files containing binary package archives. Tilde-expansion will be done on file paths.</p> <p>If this is missing or a zero-length character vector, a listbox of available packages is presented where possible in an interactive R session.</p> |
| <code>lib</code>          | character vector giving the library directories where to install the packages. Recycled as needed. If missing, defaults to the first element of <code>.libPaths()</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>repos</code>        | <p>character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as <code>"http://cran.us.r-project.org"</code>. For more details on supported URL schemes see <a href="#">url</a>.</p> <p>Can be <code>NULL</code> to install from local files, directories or URLs: this will be inferred by extension from <code>pkgs</code> if of length one.</p>                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>contriburl</code>   | URL(s) of the contrib sections of the repositories. Use this argument if your repository mirror is incomplete, e.g., because you burned only the 'contrib' section on a CD, or only have binary packages. Overrides argument <code>repos</code> . Incompatible with <code>type = "both"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>method</code>       | download method, see <a href="#">download.file</a> . Unused if a non- <code>NULL</code> available is supplied.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>available</code>    | a matrix as returned by <a href="#">available.packages</a> listing packages available at the repositories, or <code>NULL</code> when the function makes an internal call to <code>available.packages</code> . Incompatible with <code>type = "both"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>destdir</code>      | directory where downloaded packages are stored. If it is <code>NULL</code> (the default) a subdirectory <code>downloaded_packages</code> of the session temporary directory will be used (and the files will be deleted at the end of the session).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>dependencies</code> | <p>logical indicating whether to also install uninstalled packages which these packages depend on/link to/import/suggest (and so on recursively). Not used if <code>repos = NULL</code>. Can also be a character vector, a subset of <code>c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances")</code>.</p> <p>Only supported if <code>lib</code> is of length one (or missing), so it is unambiguous where to install the dependent packages. If this is not the case it is ignored, with a warning.</p> <p>The default, <code>NA</code>, means <code>c("Depends", "Imports", "LinkingTo")</code>.</p>                                                                                                                                                                  |

TRUE means to use `c("Depends", "Imports", "LinkingTo", "Suggests")` for `pkgs` and `c("Depends", "Imports", "LinkingTo")` for added dependencies: this installs all the packages needed to run `pkgs`, their examples, tests and vignettes (if the package author specified them correctly).

In all of these, "LinkingTo" is omitted for binary packages.

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>type</code>           | character, indicating the type of package to download and install. Will be "source" except on Windows and some OS X builds: see the section on 'Binary packages' for those.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>configure.args</code> | (Used only for source installs.) A character vector or a named list. If a character vector with no names is supplied, the elements are concatenated into a single string (separated by a space) and used as the value for the '--configure-args' flag in the call to <code>R CMD INSTALL</code> . If the character vector has names these are assumed to identify values for '--configure-args' for individual packages. This allows one to specify settings for an entire collection of packages which will be used if any of those packages are to be installed. (These settings can therefore be re-used and act as default settings.)<br><br>A named list can be used also to the same effect, and that allows multi-element character strings for each package which are concatenated to a single string to be used as the value for '--configure-args'. |
| <code>configure.vars</code> | (Used only for source installs.) Analogous to <code>configure.args</code> for flag '--configure-vars', which is used to set environment variables for the configure run.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>clean</code>          | a logical value indicating whether to add the '--clean' flag to the call to <code>R CMD INSTALL</code> . This is sometimes used to perform additional operations at the end of the package installation in addition to removing intermediate files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>Ncpus</code>          | the number of parallel processes to use for a parallel install of more than one source package. Values greater than one are supported if the make command specified by <code>Sys.getenv("MAKE", "make")</code> accepts argument <code>-k -j Ncpus</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>verbose</code>        | a logical indicating if some "progress report" should be given.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>libs_only</code>      | a logical value: should the '--libs-only' option be used to install only additional sub-architectures for source installs? (See also <code>INSTALL_opts</code> .) This can also be used on Windows to install just the DLL(s) from a binary package, e.g. to add 64-bit DLLs to a 32-bit install.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>INSTALL_opts</code>   | an optional character vector of additional option(s) to be passed to <code>R CMD INSTALL</code> for a source package install. E.g., <code>c("--html", "--no-multiarch")</code> .<br><br>Can also be a named list of character vectors to be used as additional options, with names the respective package names.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>quiet</code>          | logical: if true, reduce the amount of output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>keep_outputs</code>   | a logical: if true, keep the outputs from installing source packages in the current working directory, with the names of the output files the package names with '.out' appended. Alternatively, a character string giving the directory in which to save the outputs. Ignored when installing from local files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

... Arguments to be passed to [download.file](#) or to the functions for binary installs on OS X and Windows (which accept an argument "lock": see the section on 'Locking').

## Details

This is the main function to install packages. It takes a vector of names and a destination library, downloads the packages from the repositories and installs them. (If the library is omitted it defaults to the first directory in `.libPaths()`, with a message if there is more than one.) If `lib` is omitted or is of length one and is not a (group) writable directory, in interactive use the code offers to create a personal library tree (the first element of `Sys.getenv("R_LIBS_USER")`) and install there.

For installs from a repository an attempt is made to install the packages in an order that respects their dependencies. This does assume that all the entries in `lib` are on the default library path for installs (set by environment variable `R_LIBS`).

You are advised to run `update.packages` before `install.packages` to ensure that any already installed dependencies have their latest versions.

## Value

Invisible NULL.

## Binary packages

This section applies only to platforms where binary packages are available: Windows and CRAN builds for OS X.

R packages are primarily distributed as *source* packages, but *binary* packages (a packaging up of the installed package) are also supported, and the type most commonly used on Windows and by the CRAN builds for OS X. This function can install either type, either by downloading a file from a repository or from a local file.

Possible values of `type` are (currently) "source", "mac.binary", "mac.binary.mavericks" and "win.binary": the appropriate binary type where supported can also be selected as "binary".

For a binary install from a repository, the function checks for the availability of a source package on the same repository, and reports if the source package has a later version, or is available but no binary version is. This check can be suppressed by using

```
options(install.packages.check.source = "no")
```

and should be if there is a partial repository containing only binary files.

An alternative (and the current default) is "both" which means 'use binary if available and current, otherwise try source'. The action if there are source packages which are preferred but may contain code which needs to be compiled is controlled by `getOption("install.packages.compile.from.source")`. `type = "both"` will be silently changed to "binary" if either `contriburl` or `available` is specified.

Using packages with `type = "source"` always works provided the package contains no C/C++/Fortran code that needs compilation. Otherwise, on OS X you otherwise need to have installed the 'Command-line tools for Xcode' (see the 'R Installation and Administration Manual') and if needed by the package a Fortran compiler, and have them in your path.

## Locking

There are various options for locking: these differ between source and binary installs.

By default for a source install, the library directory is ‘locked’ by creating a directory ‘`00LOCK`’ within it. This has two purposes: it prevents any other process installing into that library concurrently, and is used to store any previous version of the package to restore on error. A finer-grained locking is provided by the option ‘`--pkglock`’ which creates a separate lock for each package: this allows enough freedom for parallel installation. Per-package locking is the default when installing a single package, and for multiple packages when `Ncpus > 1L`. Finally locking (and restoration on error) can be suppressed by ‘`--no-lock`’.

For an OS X or Windows binary install, no locking is done by default. Setting argument `lock` to `TRUE` (it defaults to the value of `getOption("install.lock", FALSE)`) will use per-directory locking as described for source installs: if the value is “`pkglock`” per-package locking will be used.

If package locking is used on Windows with `libs_only = TRUE` and the installation fails, the package will be restored to its previous state.

Note that it is possible for the package installation to fail so badly that the lock directory is not removed: this inhibits any further installs to the library directory (or for `--pkglock`, of the package) until the lock directory is removed manually.

## Parallel installs

Parallel installs are attempted if `pkgs` has length greater than one and `Ncpus > 1`. It makes use of a parallel make, so the make specified (default make) when `R` was built must be capable of supporting `make -j n`: GNU make, `dmake` and `pmake` do, but Solaris make and older FreeBSD make do not: if necessary environment variable `MAKE` can be set for the current session to select a suitable make.

`install.packages` needs to be able to compute all the dependencies of `pkgs` from available, including if one element of `pkgs` depends indirectly on another. This means that if for example you are installing CRAN packages which depend on Bioconductor packages which in turn depend on CRAN packages, available needs to cover both CRAN and Bioconductor packages.

## Note

Some binary distributions of `R` have `INSTALL` in a separate bundle, e.g. an R-devel RPM. `install.packages` will give an error if called with `type = "source"` on such a system.

Some binary Linux distributions of `R` can be installed on a machine without the tools needed to install packages: a possible remedy is to do a complete install of `R` which should bring in all those tools as dependencies.

## Examples

```
## Not run:
## A Linux example for Fedora's layout of udunits2 headers.
install.packages(c("ncdf4", "RNetCDF"),
  configure.args = c(RNetCDF = "--with-netcdf-include=/usr/include/udunits2"))

## End(Not run)
```

|--------------------|--------------------------------|
| installed.packages | <i>Find Installed Packages</i> |
|--------------------|--------------------------------|

---

## Description

Find (or retrieve) details of all packages installed in the specified libraries.

## Usage

```
installed.packages(lib.loc = NULL, priority = NULL,
  noCache = FALSE, fields = NULL,
  subarch = .Platform$r_arch)
```

## Arguments

|          |                                                                                                                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| lib.loc  | character vector describing the location of R library trees to search through, or NULL for all known trees (see <a href="#">.libPaths</a> ).                                                         |
| priority | character vector or NULL (default). If non-null, used to select packages; "high" is equivalent to c("base", "recommended"). To select all packages without an assigned priority use priority = "NA". |
| noCache  | Do not use cached information, nor cache it.                                                                                                                                                         |
| fields   | a character vector giving the fields to extract from each package's DESCRIPTION file in addition to the default ones, or NULL (default). Unavailable fields result in NA values.                     |
| subarch  | character string or NULL. If non-null and non-empty, used to select packages which are installed for that sub-architecture.                                                                          |

## Details

installed.packages scans the 'DESCRIPTION' files of each package found along lib.loc and returns a matrix of package names, library paths and version numbers.

The information found is cached (by library) for the R session and specified fields argument, and updated only if the top-level library directory has been altered, for example by installing or removing a package. If the cached information becomes confused, it can be refreshed by running installed.packages(noCache = TRUE).

**Value**

A matrix with one row per package, row names the package names and column names (currently) "Package", "LibPath", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS\_type", "License" and "Built" (the R version the package was built under). Additional columns can be specified using the `fields` argument.

**Note**

This can be slow when thousands of packages are installed, so do not use this to find out if a named package is installed (use [system.file](#) or [find.package](#)) nor to find out if a package is usable (call [require](#) and check the return value) nor to find details of a small number of packages (use [packageDescription](#)). It needs to read several files per installed package, which will be slow on Windows and on some network-mounted file systems.

**See Also**

[update.packages](#), [install.packages](#), [INSTALL](#), [REMOVE](#).

**Examples**

```
## confine search to .Library for speed
str(ip <- installed.packages(.Library, priority = "high"))
ip[, c(1,3:5)]
plic <- installed.packages(.Library, priority = "high", fields = "License")
## what licenses are there:
table( plic[, "License"] )
```

---

LINK

---

*Create Executable Programs*

---

**Description**

Front-end for creating executable programs.

**Usage**

```
R CMD LINK [options] linkcmd
```

**Arguments**

|                      |                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>linkcmd</code> | a list of commands to link together suitable object files (include library objects) to create the executable program. |
| <code>options</code> | further options to control the linking, or for obtaining information about usage and version.                         |

**Details**

The linker front-end is useful in particular when linking against the `R` shared or static library: see the examples.

The actual linking command is constructed by the version of `libtool` installed at `'R_HOME/bin'`.

`R CMD LINK --help` gives usage information.

**Note**

Some binary distributions of `R` have `LINK` in a separate bundle, e.g. an `R-devel` RPM.

This is not available on Windows.

**See Also**

[COMPILE](#).

**Examples**

```
## Not run: ## examples of front-ends linked against R.
## First a C program
CC=`R CMD config CC`
R CMD LINK $CC -o foo foo.o `R CMD config --ldflags`

## if Fortran code has been compiled into ForFoo.o
FLIBS=`R CMD config FLIBS`
R CMD LINK $CC -o foo foo.o ForFoo.o `R CMD config --ldflags` $FLIBS

## And for a C++ front-end
CXX=`R CMD config CXX`
R CMD COMPILE foo.cc
R CMD LINK $CXX -o foo foo.o `R CMD config --ldflags`

## End(Not run)
```

---

localeToCharset

*Select a Suitable Encoding Name from a Locale Name*

---

**Description**

This functions aims to find a suitable coding for the locale named, by default the current locale, and if it is a UTF-8 locale a suitable single-byte encoding.

**Usage**

```
localeToCharset(locale = Sys.getlocale("LC_CTYPE"))
```

**Arguments**

`locale`                      character string naming a locale.

**Details**

The operation differs by OS. Locale names are normally like `es_MX.iso88591`. If final component indicates an encoding and it is not `utf8` we just need to look up the equivalent encoding name. Otherwise, the language (here `es`) is used to choose a primary or fallback encoding.

In the C locale the answer will be `"ASCII"`.

**Value**

A character vector naming an encoding and possibly a fallback single-encoding, NA if unknown.

**Note**

The encoding names are those used by `libiconv`, and ought also to work with `glibc` but maybe not with commercial Unixen.

**See Also**

[Sys.getlocale](#), [iconv](#).

**Examples**

```
localeToCharset()
```

---

ls.str

---

*List Objects and their Structure*

---

**Description**

`ls.str` and `lsf.str` are variations of `ls` applying `str()` to each matched name: see section Value.

**Usage**

```
ls.str(pos = -1, name, envir, all.names = FALSE,
       pattern, mode = "any")

lsf.str(pos = -1, envir, ...)

## S3 method for class 'ls_str'
print(x, max.level = 1, give.attr = FALSE, ...,
      digits = max(1, getOption("str")$digits.d))
```

**Arguments**

|           |                                                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pos       | integer indicating <a href="#">search</a> path position, or -1 for the current environment.                                                                                                                                          |
| name      | optional name indicating <a href="#">search</a> path position, see <a href="#">ls</a> .                                                                                                                                              |
| envir     | environment to use, see <a href="#">ls</a> .                                                                                                                                                                                         |
| all.names | logical indicating if names which begin with a . are omitted; see <a href="#">ls</a> .                                                                                                                                               |
| pattern   | a <a href="#">regular expression</a> passed to <a href="#">ls</a> . Only names matching pattern are considered.                                                                                                                      |
| max.level | maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default 1: Display only the first nested level.                                                                       |
| give.attr | logical; if TRUE (default), show attributes as sub structures.                                                                                                                                                                       |
| mode      | character specifying the <a href="#">mode</a> of objects to consider. Passed to <a href="#">exists</a> and <a href="#">get</a> .                                                                                                     |
| x         | an object of class "ls_str".                                                                                                                                                                                                         |
| ...       | further arguments to pass. <a href="#">lsf.str</a> passes them to <a href="#">ls.str</a> which passes them on to <a href="#">ls</a> . The (non-exported) print method <code>print.ls_str</code> passes them to <a href="#">str</a> . |
| digits    | the number of significant digits to use for printing.                                                                                                                                                                                |

**Value**

[ls.str](#) and [lsf.str](#) return an object of class "ls\_str", basically the character vector of matching names (functions only for [lsf.str](#)), similarly to [ls](#), with a `print()` method that calls [str\(\)](#) on each object.

**Author(s)**

Martin Maechler

**See Also**

[str](#), [summary](#), [args](#).

**Examples**

```
require(stats)

lsf.str() #- how do the functions look like which I am using?
ls.str(mode = "list")  #- what are the structured objects I have defined?

## create a few objects
example(glm, echo = FALSE)
ll <- as.list(LETTERS)
print(ls.str(), max.level = 0)# don't show details

## which base functions have "file" in their name ?
lsf.str(pos = length(search()), pattern = "file")

## demonstrating that ls.str() works inside functions
## ["browser/debug mode"]:
```

```
tt <- function(x, y = 1) { aa <- 7; r <- x + y; ls.str() }
(nms <- sapply(strsplit(capture.output(tt(2)), " *: *"), `[`, 1))
stopifnot(nms == c("aa", "r", "x", "y"))
```

---

`maintainer`

*Show Package Maintainer*

---

## Description

Show the name and email address of the maintainer of a package.

## Usage

```
maintainer(pkg)
```

## Arguments

`pkg`                      Character string. The name of a single package.

## Details

Accesses the package description to return the name and email address of the maintainer.

Questions about contributed packages should often be addressed to the package maintainer; questions about base packages should usually be addressed to the R-help or R-devel mailing lists. Bug reports should be submitted using the [bug.report](#) function.

## Value

A character string giving the name and email address of the maintainer of the package, or NA if no such package is installed.

## Author(s)

David Scott <d.scott@auckland.ac.nz> from code on R-help originally due to Charlie Sharpsteen <source@sharpsteen.net>; multiple corrections by R-core.

## References

<https://stat.ethz.ch/pipermail/r-help/2010-February/230027.html>

## See Also

[packageDescription](#), [bug.report](#)

## Examples

```
maintainer("MASS")
```

---

|                    |                                 |
|--------------------|---------------------------------|
| make.packages.html | <i>Update HTML Package List</i> |
|--------------------|---------------------------------|

---

## Description

Re-create the HTML list of packages.

## Usage

```
make.packages.html(lib.loc = .libPaths(), temp = FALSE,  
                   verbose = TRUE, docdir = R.home("doc"))
```

## Arguments

|         |                                                                                                          |
|---------|----------------------------------------------------------------------------------------------------------|
| lib.loc | character vector. List of libraries to be included.                                                      |
| temp    | logical: should the package indices be created in a temporary location for use by the HTTP server?       |
| verbose | logical. If true, print out a message.                                                                   |
| docdir  | If temp is false, directory in whose 'html' directory the 'packages.html' file is to be created/updated. |

## Details

This creates the 'packages.html' file, either a temporary copy for use by [help.start](#), or the copy in 'R.home("doc")/html' (for which you will need write permission).

It can be very slow, as all the package 'DESCRIPTION' files in all the library trees are read.

For temp = TRUE there is some caching of information, so the file will only be re-created if lib.loc or any of the directories it lists have been changed.

## Value

Invisible logical, with FALSE indicating a failure to create the file, probably due to lack of suitable permissions.

## See Also

[help.start](#)

## Examples

```
## Not run:  
make.packages.html()  
# this can be slow for large numbers of installed packages.  
  
## End(Not run)
```

---

make.socket*Create a Socket Connection*

---

**Description**

With `server = FALSE` attempts to open a client socket to the specified port and host. With `server = TRUE` the R process listens on the specified port for a connection and then returns a server socket. It is a good idea to use [on.exit](#) to ensure that a socket is closed, as you only get 64 of them.

**Usage**

```
make.socket(host = "localhost", port, fail = TRUE, server = FALSE)
```

**Arguments**

|        |                                 |
|--------|---------------------------------|
| host   | name of remote host             |
| port   | port to connect to/listen on    |
| fail   | failure to connect is an error? |
| server | a server socket?                |

**Value**

An object of class "socket", a list with components:

|        |                                                                                   |
|--------|-----------------------------------------------------------------------------------|
| socket | socket number. This is for internal use. On a Unix-alike it is a file descriptor. |
| port   | port number of the connection.                                                    |
| host   | name of remote computer.                                                          |

**Warning**

I don't know if the connecting host name returned when `server = TRUE` can be trusted. I suspect not.

**Author(s)**

Thomas Lumley

**References**

Adapted from Luke Tierney's code for XLISP-Stat, in turn based on code from Robbins and Robbins "Practical UNIX Programming".

**See Also**

[close.socket](#), [read.socket](#).

Compiling in support for sockets is optional: see [capabilities](#)("sockets") to see if it is available.

Examples

```
daytime <- function(host = "localhost"){
  a <- make.socket(host, 13)
  on.exit(close.socket(a))
  read.socket(a)
}
## Official time (UTC) from US Naval Observatory
## Not run: daytime("tick.usno.navy.mil")
```

---

|             |                                    |
|-------------|------------------------------------|
| memory.size | <i>Report on Memory Allocation</i> |
|-------------|------------------------------------|

---

Description

memory.size and memory.limit are used to manage the total memory allocation on Windows. On other platforms these are stubs which report infinity with a warning.

Usage

```
memory.size(max = FALSE)

memory.limit(size = NA)
```

Arguments

- max                    logical. If true the maximum amount of memory obtained from the OS is reported, otherwise the amount currently in use.
- size                   numeric. If NA report the memory size, otherwise request a new limit, in Mb.

Details

To restrict memory usage on a Unix-alike use the facilities of the shell used to launch R, e.g. limit or ulimit.

Value

Size in bytes: always Inf.

See Also

[Memory-limits](#) for other limits.

---

menu

---

*Menu Interaction Function*

---

### Description

menu presents the user with a menu of choices labelled from 1 to the number of choices. To exit without choosing an item one can select '0'.

### Usage

```
menu(choices, graphics = FALSE, title = NULL)
```

### Arguments

|          |                                                                                |
|----------|--------------------------------------------------------------------------------|
| choices  | a character vector of choices                                                  |
| graphics | a logical indicating whether a graphics menu should be used if available.      |
| title    | a character string to be used as the title of the menu. NULL is also accepted. |

### Details

If graphics = TRUE and a windowing system is available (Windows, OS X or X11 *via* Tcl/Tk) a listbox widget is used, otherwise a text menu. It is an error to use menu in a non-interactive session.

Ten or fewer items will be displayed in a single column, more in multiple columns if possible within the current display width.

No title is displayed if title is NULL or "".

### Value

The number corresponding to the selected item, or 0 if no choice was made.

### References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

### See Also

[select.list](#), which is used to implement the graphical menu, and allows multiple selections.

### Examples

```
## Not run:
switch(menu(c("List letters", "List LETTERS")) + 1,
        cat("Nothing done\n"), letters, LETTERS)

## End(Not run)
```

---

 methods

---

*List Methods for S3 Generic Functions or Classes*

---

## Description

List all available methods for a S3 and S4 generic function, or all methods for an S3 or S4 class.

## Usage

```
methods(generic.function, class)
.S3methods(generic.function, class, envir=parent.frame())
```

## Arguments

|                               |                                                                                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>generic.function</code> | a generic function, or a character string naming a generic function.                                                                    |
| <code>class</code>            | a symbol or character string naming a class: only used if <code>generic.function</code> is not supplied.                                |
| <code>envir</code>            | the environment in which to look for the definition of the generic function, when the generic function is passed as a character string. |

## Details

`methods()` finds S3 and S4 methods associated with either the `generic.function` or `class` argument. Methods are found in all packages on the current `search()` path. `.S3methods()` finds only S3 methods, `.S4methods()` finds only only S4 methods.

When invoked with the `generic.function` argument, the `print` method displays the signatures (full names) of S3 and S4 methods. S3 methods are printed by pasting the generic function and class together, separated by a '.', as `generic.class`. The S3 method name is followed by an asterisk \* if the method definition is not exported from the package namespace in which the method is defined. S4 method signatures are printed as `generic,class-method`; S4 allows for multiple dispatch, so there may be several classes in the signature `generic,A,B-method`.

When invoked with the `class` argument, the `print` method displays the names of the generic functions associated with the class, `generic`.

The source code for all functions is available. For S3 functions exported from the namespace, enter the method at the command line as `generic.class`. For S3 functions not exported from the namespace, see `getAnywhere` or `getS3method`. For S4 methods, see `getMethod`.

Help is available for each method, in addition to each generic. For interactive help, use the documentation shortcut ? with the name of the generic and tab completion, ?"generic<tab>" to select the method for which help is desired.

The S3 functions listed are those which *are named like methods* and may not actually be methods (known exceptions are discarded in the code).

**Value**

An object of class "MethodsFunction", a character vector of method names with "byclass" and "info" attributes. The "byclass" attribute is a logical(1) vector with value TRUE when the results were obtained with argument class defined. The "info" attribute is a data frame with columns:

**generic** character(), the name of the generic.

**visible** logical(), is the column exported from the namespace of the package in which it is defined?

**isS4** logical(), true when the method is an S4 method.

**from** factor(), the location or package name where the method was found.

**Note**

The original methods function was written by Martin Maechler.

|-------------|------------------------------------|
| mirrorAdmin | <i>Managing Repository Mirrors</i> |
|-------------|------------------------------------|

---

**Description**

Functions helping to maintain CRAN, some of them may also be useful for administrators of other repository networks.

**Usage**

```
mirror2html(mirrors = NULL, file = "mirrors.html",  
            head = "mirrors-head.html", foot = "mirrors-foot.html")  
checkCRAN(method)
```

**Arguments**

|         |                                                            |
|---------|------------------------------------------------------------|
| mirrors | A data frame, by default the CRAN list of mirrors is used. |
| file    | A <a href="#">connection</a> or a character string.        |
| head    | Name of optional header file.                              |
| foot    | Name of optional footer file.                              |
| method  | Download method, see <code>download.file</code> .          |

**Details**

mirror2html creates the HTML file for the CRAN list of mirrors and invisibly returns the HTML text.

checkCRAN performs a sanity checks on all CRAN mirrors.

---

|            |                                              |
|------------|----------------------------------------------|
| modifyList | <i>Recursively Modify Elements of a List</i> |
|------------|----------------------------------------------|

---

**Description**

Modifies a possibly nested list recursively by changing a subset of elements at each level to match a second list.

**Usage**

```
modifyList(x, val, keep.null = FALSE)
```

**Arguments**

|           |                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------|
| x         | A named <a href="#">list</a> , possibly empty.                                                                                |
| val       | A named list with components to replace corresponding components in x.                                                        |
| keep.null | If TRUE, NULL elements in val become NULL elements in x. Otherwise, the corresponding element, if present, is deleted from x. |

**Value**

A modified version of `x`, with the modifications determined as follows (here, list elements are identified by their names). Elements in `val` which are missing from `x` are added to `x`. For elements that are common to both but are not both lists themselves, the component in `x` is replaced (or possibly deleted, depending on the value of `keep.null`) by the one in `val`. For common elements that are in both lists, `x[[name]]` is replaced by `modifyList(x[[name]], val[[name]])`.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**Examples**

```
foo <- list(a = 1, b = list(c = "a", d = FALSE))
bar <- modifyList(foo, list(e = 2, b = list(d = TRUE)))
str(foo)
str(bar)
```

---

news

*Build and Query R or Package News Information*

---

**Description**

Build and query the news for R or add-on packages.

**Usage**

```
news(query, package = "R", lib.loc = NULL, format = NULL,
      reader = NULL, db = NULL)
```

**Arguments**

|                      |                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>query</code>   | an expression for selecting news entries                                                                                               |
| <code>package</code> | a character string giving the name of an installed add-on package, or "R".                                                             |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. |
| <code>format</code>  | Not yet used.                                                                                                                          |
| <code>reader</code>  | Not yet used.                                                                                                                          |
| <code>db</code>      | a news db obtained from <code>news()</code> .                                                                                          |

## Details

If package is "R" (default), a news db is built with the news since the 3.0.0 release of R (corresponding to R's top-level 'NEWS' file). Otherwise, if the given add-on package can be found in the given libraries, it is attempted to read its news in structured form from files 'inst/NEWS.Rd', 'NEWS' or 'inst/NEWS' (in that order).

File 'inst/NEWS.Rd' should be an Rd file given the entries as Rd \itemize lists, grouped according to version using section elements with names starting with a suitable prefix (e.g. "Changes in version" followed by a space and the version number, and optionally followed by a space and a parenthesized ISO 8601 (%Y-%m-%d, see [strptime](#)) format date, and possibly further grouped according to categories using \subsection elements named as the categories. At the very end of \section{..}, the date may also be specified as (%Y-%m-%d, <note>), i.e., including parentheses.

The plain text 'NEWS' files in add-on packages use a variety of different formats; the default news reader should be capable to extract individual news entries from a majority of packages from the standard repositories, which use (slight variations of) the following format:

- Entries are grouped according to version, with version header "Changes in version" at the beginning of a line, followed by a version number, optionally followed by an ISO 8601 format date, possibly parenthesized.
- Entries may be grouped according to category, with a category header (different from a version header) starting at the beginning of a line.
- Entries are written as itemize-type lists, using one of 'o', '\*', '-' or '+' as item tag. Entries must be indented, and ideally use a common indentation for the item texts.

Additional formats and readers may be supported in the future.

Package **tools** provides an (internal) utility function `news2Rd` to convert plain text 'NEWS' files to Rd. For 'NEWS' files in a format which can successfully be handled by the default reader, package maintainers can use `tools::news2Rd(dir, "NEWS.Rd")`, possibly with additional argument `codify = TRUE`, with `dir` a character string specifying the path to a package's root directory. Upon success, the 'NEWS.Rd' file can further be improved and then be moved to the 'inst' subdirectory of the package source directory.

The news db built is a character data frame inheriting from "news\_db" with variables `Version`, `Category`, `Date` and `Text`, where the last contains the entry texts read, and the other variables may be NA if they were missing or could not be determined.

Using `query`, one can select news entries from the db. If missing or NULL, the complete db is returned. Otherwise, `query` should be an expression involving (a subset of) the variables `Version`, `Category`, `Date` and `Text`, and when evaluated within the db returning a logical vector with length the number of entries in the db. The entries for which evaluation gave TRUE are selected. When evaluating, `Version` and `Date` are coerced to [numeric\\_version](#) and [Date](#) objects, respectively, so that the comparison operators for these classes can be employed.

## Value

An data frame inheriting from class "news\_db".

**Examples**

```
## Build a db of all R news entries.
db <- news()

## Bug fixes with PR number in 3.0.1.
db3 <- news(Version == "3.0.1" & grepl("^BUG", Category) & grepl("PR#", Text),
           db = db)

## News from a date range ('Matrix' is there in a regular R installation):
if(length(iM <- find.package("Matrix", quiet=TRUE)) && nzchar(iM)) {
  dM <- news(package="Matrix")
  dM2014 <- news("2014-01-01" <= Date & Date <= "2014-12-31", db = dM)
  stopifnot(paste0("1.1-", 2:4) %in% dM2014[, "Version"])
}

## Which categories have been in use? % R-core maybe should standardize a bit more
sort(table(db[, "Category"]), decreasing = TRUE)
## Entries with version >= 3.0.0 (including "3.0.0 patched"):
table(news(Version >= "3.0.0", db = db)$Version)
```

nsl

*Look up the IP Address by Hostname***Description**

Interface to gethostbyname.

**Usage**

```
nsl(hostname)
```

**Arguments**

hostname            the name of the host.

**Details**

This was included as a test of internet connectivity, to fail if the node running R is not connected. It will also return NULL if BSD networking is not supported, including the header file ‘arpa/inet.h’.

This function is not available on Windows.

**Value**

The IP address, as a character string, or NULL if the call fails.

**Examples**

```
## Not run: nsl("www.r-project.org")
```

---

object.size

*Report the Space Allocated for an Object*

---

### Description

Provides an estimate of the memory that is being used to store an R object.

### Usage

```
object.size(x)

## S3 method for class 'object_size'
format(x, units = "b", ...)
## S3 method for class 'object_size'
print(x, quote = FALSE, units = "b", ...)
```

### Arguments

|       |                                                                                                                                                             |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x     | An R object.                                                                                                                                                |
| quote | logical, indicating whether or not the result should be printed with surrounding quotes.                                                                    |
| units | The units to be used in printing the size. Allowed values are "b", "Kb", "Mb", "Gb", "B", "KB", "MB", "GB", and "auto" (see 'Details'). Can be abbreviated. |
| ...   | Arguments to be passed to or from other methods.                                                                                                            |

### Details

Exactly which parts of the memory allocation should be attributed to which object is not clear-cut. This function merely provides a rough indication: it should be reasonably accurate for atomic vectors, but does not detect if elements of a list are shared, for example. (Sharing amongst elements of a character vector is taken into account, but not that between character vectors in a single object.)

The calculation is of the size of the object, and excludes the space needed to store its name in the symbol table.

Associated space (e.g., the environment of a function and what the pointer in a EXTPTRSXP points to) is not included in the calculation.

Object sizes are larger on 64-bit builds than 32-bit ones, but will very likely be the same on different platforms with the same word length and pointer size.

units = "auto" in the format and print methods chooses the largest units in which the result is one or more (before rounding). Values in kilobytes, megabytes or gigabytes are rounded to the nearest 0.1.

### Value

An object of class "object\_size" with a length-one double value, an estimate of the memory allocation attributable to the object in bytes.

**See Also**

[Memory-limits](#) for the design limitations on object size.

**Examples**

```
object.size(letters)
object.size(ls)
format(object.size(library), units = "auto")
## find the 10 largest objects in the base package
z <- sapply(ls("package:base"), function(x)
  object.size(get(x, envir = baseenv())))
as.matrix(rev(sort(z))[1:10])
```

---

package.skeleton

---

*Create a Skeleton for a New Source Package*

---

**Description**

package.skeleton automates some of the setup for a new source package. It creates directories, saves functions, data, and R code files to appropriate places, and creates skeleton help files and a ‘Read-and-delete-me’ file describing further steps in packaging.

**Usage**

```
package.skeleton(name = "anRpackage", list,
  environment = .GlobalEnv,
  path = ".", force = FALSE,
  code_files = character())
```

**Arguments**

|             |                                                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| name        | character string: the package name and directory name for your package.                                                                                |
| list        | character vector naming the R objects to put in the package. Usually, at most one of list, environment, or code_files will be supplied. See ‘Details’. |
| environment | an environment where objects are looked for. See ‘Details’.                                                                                            |
| path        | path to put the package directory in.                                                                                                                  |
| force       | If FALSE will not overwrite an existing directory.                                                                                                     |
| code_files  | a character vector with the paths to R code files to build the package around. See ‘Details’.                                                          |

## Details

The arguments `list`, `environment`, and `code_files` provide alternative ways to initialize the package. If `code_files` is supplied, the files so named will be sourced to form the environment, then used to generate the package skeleton. Otherwise `list` defaults to the objects in `environment` (including those whose names start with `.`), but can be supplied to select a subset of the objects in that environment.

Stubs of help files are generated for functions, data objects, and S4 classes and methods, using the `prompt`, `promptClass`, and `promptMethods` functions. If an object from another package is intended to be imported and re-exported without changes, the `promptImport` function should be used after `package.skeleton` to generate a simple help file linking to the original one.

The package sources are placed in subdirectory `name` of `path`. If `code_files` is supplied, these files are copied; otherwise, objects will be dumped into individual source files. The file names in `code_files` should have suffix `".R"` and be in the current working directory.

The filenames created for source and documentation try to be valid for all OSes known to run R. Invalid characters are replaced by `'_'`, invalid names are preceded by `'zz'`, names are converted to lower case (to avoid case collisions on case-insensitive file systems) and finally the converted names are made unique by `make.unique(sep = "_")`. This can be done for code and help files but not data files (which are looked for by name). Also, the code and help files should have names starting with an ASCII letter or digit, and this is checked and if necessary `z` prepended.

Functions with names starting with a dot are placed in file `'R/name-internal.R'`.

When you are done, delete the `'Read-and-delete-me'` file, as it should not be distributed.

## Value

Used for its side-effects.

## References

Read the `'Writing R Extensions'` manual for more details.

Once you have created a *source* package you need to install it: see the `'R Installation and Administration'` manual, [INSTALL](#) and [install.packages](#).

## See Also

[prompt](#), [promptClass](#), and [promptMethods](#).

## Examples

```
require(stats)
## two functions and two "data sets" :
f <- function(x, y) x+y
g <- function(x, y) x-y
d <- data.frame(a = 1, b = 2)
e <- rnorm(1000)

package.skeleton(list = c("f", "g", "d", "e"), name = "mypkg")
```

---

|                    |                            |
|--------------------|----------------------------|
| packageDescription | <i>Package Description</i> |
|--------------------|----------------------------|

---

## Description

Parses and returns the ‘DESCRIPTION’ file of a package.

## Usage

```
packageDescription(pkg, lib.loc = NULL, fields = NULL,
                  drop = TRUE, encoding = "")
packageVersion(pkg, lib.loc = NULL)
```

## Arguments

|          |                                                                                                                                                                                                                                      |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkg      | a character string with the package name.                                                                                                                                                                                            |
| lib.loc  | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages and namespaces are searched before the libraries. |
| fields   | a character vector giving the tags of fields to return (if other fields occur in the file they are ignored).                                                                                                                         |
| drop     | If TRUE and the length of fields is 1, then a single character string with the value of the respective field is returned instead of an object of class "packageDescription".                                                         |
| encoding | If there is an Encoding field, to what encoding should re-encoding be attempted? If NA, no re-encoding. The other values are as used by <a href="#">iconv</a> , so the default "" indicates the encoding of the current locale.      |

## Details

A package will not be ‘found’ unless it has a ‘DESCRIPTION’ file which contains a valid Version field. Different warnings are given when no package directory is found and when there is a suitable directory but no valid ‘DESCRIPTION’ file.

An [attached](#) environment named to look like a package (e.g., `package:utils2`) will be ignored.

`packageVersion()` is a convenience shortcut, allowing things like `if (packageVersion("MASS") < "7.3") { do.things }`.

## Value

If a ‘DESCRIPTION’ file for the given package is found and can successfully be read, `packageDescription` returns an object of class "packageDescription", which is a named list with the values of the (given) fields as elements and the tags as names, unless `drop = TRUE`.

If parsing the ‘DESCRIPTION’ file was not successful, it returns a named list of NAs with the field tags as names if fields is not null, and NA otherwise.

`packageVersion()` returns a (length-one) object of class "[package\\_version](#)".

**See Also**[read.dcf](#)**Examples**

```

packageDescription("stats")
packageDescription("stats", fields = c("Package", "Version"))

packageDescription("stats", fields = "Version")
packageDescription("stats", fields = "Version", drop = FALSE)

if(packageVersion("MASS") < "7.3.29")
  message("you need to update 'MASS'")

```

packageName

*Find package associated with an environment.***Description**

Many environments are associated with a package; this function attempts to determine that package.

**Usage**

```
packageName(env = parent.frame())
```

**Arguments**

env                    The environment whose name we seek.

**Details**

Environment env would be associated with a package if [topenv](#)(env) is the namespace environment for that package. Thus when env is the environment associated with functions inside a package, or local functions defined within them, packageName will normally return the package name.

Not all environments are associated with a package: for example, the global environment, or the evaluation frames of functions defined there. packageName will return NULL in these cases.

**Value**

A length one character vector containing the name of the package, or NULL if there is no name.

**See Also**

[getPackageName](#) is a more elaborate function that can construct a name if none is found.

**Examples**

```

packageName()
packageName(environment(mean))

```

---

|               |                                 |
|---------------|---------------------------------|
| packageStatus | <i>Package Management Tools</i> |
|---------------|---------------------------------|

---

**Description**

Summarize information about installed packages and packages available at various repositories, and automatically upgrade outdated packages.

**Usage**

```
packageStatus(lib.loc = NULL, repositories = NULL, method,
              type = getOption("pkgType"))

## S3 method for class 'packageStatus'
summary(object, ...)

## S3 method for class 'packageStatus'
update(object, lib.loc = levels(object$inst$LibPath),
        repositories = levels(object$avail$Repository), ...)

## S3 method for class 'packageStatus'
upgrade(object, ask = TRUE, ...)
```

**Arguments**

|              |                                                                                                                                                                   |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| lib.loc      | a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known. |
| repositories | a character vector of URLs describing the location of R package repositories on the Internet or on the local machine.                                             |
| method       | Download method, see <a href="#">download.file</a> .                                                                                                              |
| type         | type of package distribution: see <a href="#">install.packages</a> .                                                                                              |
| object       | an object of class "packageStatus" as returned by packageStatus.                                                                                                  |
| ask          | if TRUE, the user is prompted which packages should be upgraded and which not.                                                                                    |
| ...          | currently not used.                                                                                                                                               |

**Details**

The URLs in repositories should be full paths to the appropriate contrib sections of the repositories. The default is `contrib.url(getOption("repos"))`.

There are print and summary methods for the "packageStatus" objects: the print method gives a brief tabular summary and the summary method prints the results.

The update method updates the "packageStatus" object. The upgrade method is similar to [update.packages](#): it offers to install the current versions of those packages which are not currently up-to-date.

**Value**

An object of class "packageStatus". This is a list with two components

|       |                                                                                                                                                                                                                                                                        |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| inst  | a data frame with columns as the <i>matrix</i> returned by <a href="#">installed.packages</a> plus "Status", a factor with levels c("ok", "upgrade", "unavailable"). Only the newest version of each package is reported, in the first repository in which it appears. |
| avail | a data frame with columns as the <i>matrix</i> returned by <a href="#">available.packages</a> plus "Status", a factor with levels c("installed", "not installed").                                                                                                     |

For the summary method the result is also of class "summary.packageStatus" with additional components

|       |                                             |
|-------|---------------------------------------------|
| Libs  | a list with one element for each library    |
| Repos | a list with one element for each repository |

with the elements being lists of character vectors of package name for each status.

**See Also**

[installed.packages](#), [available.packages](#)

**Examples**

```
## Not run:
x <- packageStatus()
print(x)
summary(x)
upgrade(x)
x <- update(x)
print(x)

## End(Not run)
```

---

page

---

*Invoke a Pager on an R Object*

---

**Description**

Displays a representation of the object named by x in a pager via [file.show](#).

**Usage**

```
page(x, method = c("dput", "print"), ...)
```

**Arguments**

|        |                                                                                                                                                                                          |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | An R object, or a character string naming an object.                                                                                                                                     |
| method | The default method is to dump the object <i>via</i> <code>dput</code> . An alternative is to use <code>print</code> and capture the output to be shown in the pager. Can be abbreviated. |
| ...    | additional arguments for <code>dput</code> , <code>print</code> or <code>file.show</code> (such as <code>title</code> ).                                                                 |

**Details**

If `x` is a length-one character vector, it is used as the name of an object to look up in the environment from which `page` is called. All other objects are displayed directly.

A default value of `title` is passed to `file.show` if one is not supplied in ....

**See Also**

`file.show`, `edit`, `fix`.

To go to a new page when graphing, see `frame`.

**Examples**

```
## Not run: ## four ways to look at the code of 'page'
page(page)           # as an object
page("page")        # a character string
v <- "page"; page(v)  # a length-one character vector
page(utils::page)    # a call

## End(Not run)
```

---

person

*Persons*

---

**Description**

A class and utility methods for holding information about persons like name and email address.

**Usage**

```
person(given = NULL, family = NULL, middle = NULL,
       email = NULL, role = NULL, comment = NULL,
       first = NULL, last = NULL)
## Default S3 method:
as.person(x)
## S3 method for class 'person'
format(x,
      include = c("given", "family", "email", "role", "comment"),
      braces = list(given = "", family = "", email = c("<", ">"),
                    role = c("[", "]"), comment = c("(", ")")),
```

```
collapse = list(given = " ", family = " ", email = " ",
               role = " ", comment = " "),
...,
style = c("text", "R")
)
```

## Arguments

|                       |                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------|
| <code>given</code>    | a character vector with the <i>given</i> names, or a list thereof.                                       |
| <code>family</code>   | a character string with the <i>family</i> name, or a list thereof.                                       |
| <code>middle</code>   | a character string with the collapsed middle name(s). Deprecated, see <b>Details</b> .                   |
| <code>email</code>    | a character string giving the email address, or a list thereof.                                          |
| <code>role</code>     | a character string specifying the role of the person (see <b>Details</b> ), or a list thereof.           |
| <code>comment</code>  | a character string providing a comment, or a list thereof.                                               |
| <code>first</code>    | a character string giving the first name. Deprecated, see <b>Details</b> .                               |
| <code>last</code>     | a character string giving the last name. Deprecated, see <b>Details</b> .                                |
| <code>x</code>        | a character string for the <code>as.person</code> default method; an object of class "person" otherwise. |
| <code>include</code>  | a character vector giving the fields to be included when formatting.                                     |
| <code>braces</code>   | a list of characters (see <b>Details</b> ).                                                              |
| <code>collapse</code> | a list of characters (see <b>Details</b> ).                                                              |
| <code>...</code>      | currently not used.                                                                                      |
| <code>style</code>    | a character string specifying the print style, with "R" yielding formatting as R code.                   |

## Details

Objects of class "person" can hold information about an arbitrary positive number of persons. These can be obtained by one call to `person()` with list arguments, or by first creating objects representing single persons and combining these via `c()`.

The `format()` method collapses information about persons into character vectors (one string for each person): the fields in `include` are selected, each collapsed to a string using the respective element of `collapse` and subsequently "embraced" using the respective element of `braces`, and finally collapsed into one string separated by white space. If `braces` and/or `collapse` do not specify characters for all fields, the defaults shown in the usage are imputed. The `print()` method calls the `format()` method and prints the result, the `toBibtex()` method creates a suitable BibTeX representation.

Person objects can be subscripted by fields (using `$`) or by position (using `[]`).

`as.person()` is a generic function. Its default method tries to reverse the default person formatting, and can also handle formatted person entries collapsed by comma or "and" (with appropriate white space).

Personal names are rather tricky, e.g., [https://en.wikipedia.org/wiki/Personal\\_name](https://en.wikipedia.org/wiki/Personal_name).

The current implementation (starting from R 2.12.0) of the "person" class uses the notions of *given* (including middle names) and *family* names, as specified by `given` and `family` respectively. Earlier

versions used a scheme based on first, middle and last names, as appropriate for most of Western culture where the given name precedes the family name, but not universal, as some other cultures place it after the family name, or use no family name. To smooth the transition to the new scheme, arguments `first`, `middle` and `last` are still supported, but their use is deprecated and they must not be given in combination with the corresponding new style arguments. For persons which are not natural persons (e.g., institutions, companies, etc.) it is appropriate to use `given` (but not `family`) for the name, e.g., `person("R Core Team", role = "aut")`.

The new scheme also adds the possibility of specifying *roles* based on a subset of the MARC Code List for Relators (<https://www.loc.gov/marc/relators/relaterm.html>). When giving the roles of persons in the context of authoring R packages, the following usage is suggested.

"aut" (Author) Use for full authors who have made substantial contributions to the package and should show up in the package citation.

"com" (Compiler) Use for persons who collected code (potentially in other languages) but did not make further substantial contributions to the package.

"ctb" (Contributor) Use for authors who have made smaller contributions (such as code patches etc.) but should not show up in the package citation.

"cph" (Copyright holder) Use for all copyright holders.

"cre" (Creator) Use for the package maintainer.

"ctr" (Contractor) Use for authors who have been contracted to write (parts of) the package and hence do not own intellectual property.

"dtc" (Data contributor) Use for persons who contributed data sets for the package.

"ths" (Thesis advisor) If the package is part of a thesis, use for the thesis advisor.

"trl" (Translator) If the R code is a translation from another language (typically S), use for the translator to R.

In the old scheme, person objects were used for single persons, and a separate `personList` class with corresponding creator `personList()` for collections of these. The new scheme employs a single class for information about an arbitrary positive number of persons, eliminating the need for the `personList` mechanism.

## Value

`person()` and `as.person()` return objects of class `"person"`.

## See Also

[citation](#)

## Examples

```
## Create a person object directly ...
p1 <- person("Karl", "Pearson", email = "pearson@stats.heaven")

## ... or convert a string.
p2 <- as.person("Ronald Aylmer Fisher")

## Combining and subsetting.
```

```

p <- c(p1, p2)
p[1]
p[-1]

## Extracting fields.
p$family
p$email
p[1]$email

## Specifying package authors, example from "boot":
## AC is the first author [aut] who wrote the S original.
## BR is the second author [aut], who translated the code to R [trl],
## and maintains the package [cre].
b <- c(person("Angelo", "Canty", role = "aut", comment =
  "S original, http://statwww.epfl.ch/davison/BMA/library.html"),
  person(c("Brian", "D."), "Ripley", role = c("aut", "trl", "cre"),
    comment = "R port", email = "ripley@stats.ox.ac.uk")
  )
b

## Formatting.
format(b)
format(b, include = c("family", "given", "role"),
  braces = list(family = c("", "", ""), role = c("Role(s): ", "")))

## Conversion to BibTeX author field.
paste(format(b, include = c("given", "family")), collapse = " and ")
toBibtex(b)

```

---

PkgUtils

*Utilities for Building and Checking Add-on Packages*

---

## Description

Utilities for checking whether the sources of an R add-on package work correctly, and for building a source package from them.

## Usage

```

R CMD check [options] pkgdirs
R CMD build [options] pkgdirs

```

## Arguments

|         |                                                                                                                                                                                                                                                          |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgdirs | a list of names of directories with sources of R add-on packages. For check these can also be the filenames of compressed tar archives with extension <code>‘.tar.gz’</code> , <code>‘.tgz’</code> , <code>‘.tar.bz2’</code> or <code>‘.tar.xz’</code> . |
| options | further options to control the processing, or for obtaining information about usage and version of the utility.                                                                                                                                          |

## Details

R CMD check checks R add-on packages from their sources, performing a wide variety of diagnostic checks.

R CMD build builds R source tarballs. The name(s) of the packages are taken from the ‘DESCRIPTION’ files and not from the directory names. This works entirely on a copy of the supplied source directories.

Use R CMD foo --help to obtain usage information on utility foo.

The defaults for some of the options to R CMD build can be set by environment variables `_R_BUILD_RESAVE_DATA_` and `_R_BUILD_COMPACT_VIGNETTES_`: see ‘Writing R Extensions’. Many of the checks in R CMD check can be turned off or on by environment variables: see Chapter 6 of the ‘R Internals’ manual.

By default R CMD build uses the “internal” option to `tar` to prepare the tarball. An external tar program can be specified by the `R_BUILD_TAR` environment variable. This may be substantially faster for very large packages, and can be needed for packages with long path names (over 100 bytes) or very large files (over 8GB): however, the resulting tarball may not be portable.

R CMD check by default unpacks tarballs by the internal `untar` function: if needed an external tar command can be specified by the environment variable `R_INSTALL_TAR`: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting `R_INSTALL_TAR` to ‘tar.exe’ has been needed to overcome permissions issues on some Windows systems.)

---

|                |                               |
|----------------|-------------------------------|
| process.events | <i>Trigger event handling</i> |
|----------------|-------------------------------|

---

## Description

R front ends like the Windows GUI handle key presses and mouse clicks through “events” generated by the OS. These are processed automatically by R at intervals during computations, but in some cases it may be desirable to trigger immediate event handling. The `process.events` function does that.

## Usage

```
process.events()
```

## Details

This is a simple wrapper for the C API function `R_ProcessEvents`. As such, it is possible that it will not return if the user has signalled to interrupt the calculation.

**Value**

NULL is returned invisibly.

**Author(s)**

Duncan Murdoch

**See Also**

See ‘Writing R Extensions’ and the ‘R for Windows FAQ’ for more discussion of the `R_ProcessEvents` function.

---

prompt

*Produce Prototype of an R Documentation File*

---

**Description**

Facilitate the constructing of files documenting R objects.

**Usage**

```
prompt(object, filename = NULL, name = NULL, ...)
```

```
## Default S3 method:
```

```
prompt(object, filename = NULL, name = NULL,
       force.function = FALSE, ...)
```

```
## S3 method for class 'data.frame'
```

```
prompt(object, filename = NULL, name = NULL, ...)
```

```
promptImport(object, filename = NULL, name = NULL,
             importedFrom = NULL, importPage = name, ...)
```

**Arguments**

|                             |                                                                                                                                                                                                                                                 |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>         | an R object, typically a function for the default method. Can be <a href="#">missing</a> when name is specified.                                                                                                                                |
| <code>filename</code>       | usually, a <a href="#">connection</a> or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by “.Rd”. Can also be NA (see below). |
| <code>name</code>           | a character string specifying the name of the object.                                                                                                                                                                                           |
| <code>force.function</code> | a logical. If TRUE, treat object as function in any case.                                                                                                                                                                                       |
| <code>...</code>            | further arguments passed to or from other methods.                                                                                                                                                                                              |
| <code>importedFrom</code>   | a character string naming the package from which object was imported. Defaults to the environment of object if object is a function.                                                                                                            |
| <code>importPage</code>     | a character string naming the help page in the package from which object was imported.                                                                                                                                                          |

## Details

Unless `filename` is `NA`, a documentation shell for `object` is written to the file specified by `filename`, and a message about this is given. For function objects, this shell contains the proper function and argument names. R documentation files thus created still need to be edited and moved into the ‘man’ subdirectory of the package containing the object to be documented.

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where `x` is the list-style representation.

When `prompt` is used in `for` loops or scripts, the explicit name specification will be useful.

The `importPage` argument for `promptImport` needs to give the base of the name of the help file of the original help page. For example, the `approx` function is documented in ‘`approxfun.Rd`’ in the **stats** package, so if it were imported and re-exported it should have `importPage = "approxfun"`. Objects that are imported from other packages are not normally documented unless re-exported.

## Value

If `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

## Warning

The default filename may not be a valid filename under limited file systems (e.g., those on Windows).

Currently, calling `prompt` on a non-function object assumes that the object is in fact a data set and hence documents it as such. This may change in future versions of R. Use `promptData` to create documentation skeletons for data sets.

## Note

The documentation file produced by `prompt.data.frame` does not have the same format as many of the data frame documentation files in the **base** package. We are trying to settle on a preferred format for the documentation.

## Author(s)

Douglas Bates for `prompt.data.frame`

## References

For creation of many help pages (for a package), see `package.skeleton`.

To prompt the user for input, see `readline`.

**Examples**

```

require(graphics)
prompt(plot.default)
prompt(interactive, force.function = TRUE)
unlink("plot.default.Rd")
unlink("interactive.Rd")

prompt(women) # data.frame
unlink("women.Rd")

prompt(sunspots) # non-data.frame data
unlink("sunspots.Rd")

## Not run:
## Create a help file for each function in the .GlobalEnv:
for(f in ls()) if(is.function(get(f))) prompt(name = f)

## End(Not run)

```

---

promptData

---

*Generate Outline Documentation for a Data Set*

---

**Description**

Generates a shell of documentation for a data set.

**Usage**

```
promptData(object, filename = NULL, name = NULL)
```

**Arguments**

|          |                                                                                                                                                                                                                                                 |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object   | an R object to be documented as a data set.                                                                                                                                                                                                     |
| filename | usually, a <a href="#">connection</a> or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be NA (see below). |
| name     | a character string specifying the name of the object.                                                                                                                                                                                           |

**Details**

Unless filename is NA, a documentation shell for object is written to the file specified by filename, and a message about this is given.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where x is the list-style representation.

Currently, only data frames are handled explicitly by the code.

**Value**

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

**See Also**

**Examples**

```
promptData(sunspots)
unlink("sunspots.Rd")
```

---

promptPackage

*Generate a Shell for Documentation of a Package*

---

**Description**

Generates a shell of documentation for an installed or source package.

**Usage**

```
promptPackage(package, lib.loc = NULL, filename = NULL,
              name = NULL, final = FALSE)
```

**Arguments**

|          |                                                                                                                                                                                                                                                           |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package  | a <a href="#">character</a> string with the name of an <i>installed</i> or <i>source</i> package to be documented.                                                                                                                                        |
| lib.loc  | a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known. For a source package this should specify the parent directory of the package's sources. |
| filename | usually, a <a href="#">connection</a> or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be NA (see below).           |
| name     | a character string specifying the name of the help topic, typically of the form '<pkg>-package'.                                                                                                                                                          |
| final    | a logical value indicating whether to attempt to create a usable version of the help topic, rather than just a shell.                                                                                                                                     |

**Details**

Unless `filename` is `NA`, a documentation shell for package is written to the file specified by `filename`, and a message about this is given.

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where `x` is the list-style representation.

If `final` is `TRUE`, the generated documentation will not include the place-holder slots for manual editing, it will be usable as-is. In most cases a manually edited file is preferable (but `final = TRUE` is certainly less work).

**Value**

If `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

Question

*Documentation Shortcuts*

---

**Description**

These functions provide access to documentation. Documentation on a topic with name `name` (typically, an R object or a data set) can be displayed by either `help("name")` or `?name`.

**Usage**

`?topic`

`type?topic`

## Arguments

|       |                                                                                                                                                                                                                                                                                                                                                                                     |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| topic | Usually, a <a href="#">name</a> or character string specifying the topic for which help is sought. Alternatively, a function call to ask for documentation on a corresponding S4 method: see the section on S4 method documentation. The calls <code>pkg::topic</code> and <code>pkg:::topic</code> are treated specially, and look for help on topic in package <code>pkg</code> . |
| type  | the special type of documentation to use for this topic; for example, if the type is <code>class</code> , documentation is provided for the class with name <code>topic</code> . See the Section ‘S4 Method Documentation’ for the uses of <code>type</code> to get help on formal methods, including <code>methods?function</code> and <code>method?call</code> .                  |

## Details

This is a shortcut to [help](#) and uses its default type of help.

Some topics need to be quoted (by [backticks](#)) or given as a character string. There include those which cannot syntactically appear on their own such as unary and binary operators, `function` and control-flow [reserved](#) words (including `if`, `else`, `for`, `in`, `repeat`, `while`, `break` and `next`). The other reserved words can be used as if they were names, for example `TRUE`, `NA` and `Inf`.

## S4 Method Documentation

Authors of formal (‘S4’) methods can provide documentation on specific methods, as well as overall documentation on the methods of a particular function. The `"?"` operator allows access to this documentation in three ways.

The expression `methods?f` will look for the overall documentation methods for the function `f`. Currently, this means the documentation file containing the alias `f-methods`.

There are two different ways to look for documentation on a particular method. The first is to supply the `topic` argument in the form of a function call, omitting the `type` argument. The effect is to look for documentation on the method that would be used if this function call were actually evaluated. See the examples below. If the function is not a generic (no S4 methods are defined for it), the help reverts to documentation on the function name.

The `"?"` operator can also be called with `doc_type` supplied as method; in this case also, the `topic` argument is a function call, but the arguments are now interpreted as specifying the class of the argument, not the actual expression that will appear in a real call to the function. See the examples below.

The first approach will be tedious if the actual call involves complicated expressions, and may be slow if the arguments take a long time to evaluate. The second approach avoids these issues, but you do have to know what the classes of the actual arguments will be when they are evaluated.

Both approaches make use of any inherited methods; the signature of the method to be looked up is found by using `selectMethod` (see the documentation for [getMethod](#)).

?? for finding help pages on a vague topic.

**Examples**

```
?lapply

?"for"          # but quotes/backticks are needed
?"`+`

?women          # information about data set "women"

## Not run:
require(methods)
## define a S4 generic function and some methods
combo <- function(x, y) c(x, y)
setGeneric("combo")
setMethod("combo", c("numeric", "numeric"), function(x, y) x+y)

## assume we have written some documentation
## for combo, and its methods ....

?combo # produces the function documentation

methods?combo # looks for the overall methods documentation

method?combo("numeric", "numeric") # documentation for the method above

?combo(1:10, rnorm(10)) # ... the same method, selected according to
                        # the arguments (one integer, the other numeric)

?combo(1:10, letters)  # documentation for the default method

## End(Not run)
```

---

rcompgen*A Completion Generator for R*

---

**Description**

This page documents a mechanism to generate relevant completions from a partially completed command line. It is not intended to be useful by itself, but rather in conjunction with other mechanisms that use it as a backend. The functions listed in the usage section provide a simple control and query mechanism. The actual interface consists of a few unexported functions described further down.

## Usage

```
rc.settings(ops, ns, args, func, ipck, S3, data, help,
            argdb, fuzzy, quotes, files)

rc.status()
rc.getOption(name)
rc.options(...)

.DollarNames(x, pattern)

## Default S3 method:
.DollarNames(x, pattern = "")
## S3 method for class 'list'
.DollarNames(x, pattern = "")
## S3 method for class 'environment'
.DollarNames(x, pattern = "")
```

## Arguments

**ops, ns, args, func, ipck, S3, data, help, argdb, fuzzy, quotes, files**  
logical, turning some optional completion features on and off.

**ops:** Activates completion after the \$ and @ operators.

**ns:** Controls namespace related completions.

**args:** Enables completion of function arguments.

**func:** Enables detection of functions. If enabled, a customizable extension ("(" by default) is appended to function names. The process of determining whether a potential completion is a function requires evaluation, including for lazy loaded symbols. This is undesirable for large objects, because of potentially wasteful use of memory in addition to the time overhead associated with loading. For this reason, this feature is disabled by default.

**S3:** When `args = TRUE`, activates completion on arguments of all S3 methods (otherwise just the generic, which usually has very few arguments).

**ipck:** Enables completion of installed package names inside `library` and `require`.

**data:** Enables completion of data sets (including those already visible) inside `data`.

**help:** Enables completion of help requests starting with a question mark, by looking inside help index files.

**argdb:** When `args = TRUE`, completion is attempted on function arguments. Generally, the list of valid arguments is determined by dynamic calls to `args`. While this gives results that are technically correct, the use of the `...` argument often hides some useful arguments. To give more flexibility in this regard, an optional table of valid arguments names for specific functions is retained internally. Setting `argdb = TRUE` enables preferential lookup in this internal data base for functions with an entry in it. Of

course, this is useful only when the data base contains information about the function of interest. Some functions are already included, and more can be added by the user through the unexported function `.addFunctionInfo` (see below).

**fuzzy:** Enables fuzzy matching, where close but non-exact matches (e.g., with different case) are considered if no exact matches are found. This feature is experimental and the details can change.

**quotes:** Enables completion in R code when inside quotes. This normally leads to filename completion, but can be otherwise depending on context (for example, when the open quote is preceded by `?`, help completion is invoked. Setting this to `FALSE` relegates completion to the underlying completion front-end, which may do its own processing (for example, readline on Unix-alikes will do filename completion).

**files:** Deprecated. Use quotes instead.

All settings are turned on by default except `ipck`, `func`, and `fuzzy`. Turn more off if your CPU cycles are valuable; you will still retain basic completion on names of objects in the search list. See below for additional details.

`name, ...` user-settable options. Currently valid names are

`function.suffix:` default `"(" "`

`funarg.suffix:` default `" = "`

`package.suffix` default `": : "`

Usage is similar to that of [options](#).

`x` An R object for which valid names after `"$"` are computed and returned.

`pattern` A regular expression. Only matching names are returned.

## Details

There are several types of completion, some of which can be disabled using `rc.settings`. The most basic level, which can not be turned off once the completion functionality is activated, provides completion on names visible on the search path, along with a few special keywords (e.g., `TRUE`). This type of completion is not attempted if the partial ‘word’ (a.k.a. token) being completed is empty (since there would be too many completions). The more advanced types of completion are described below.

**Completion after extractors `$` and `@`:** When the `ops` setting is turned on, completion after `$` and `@` is attempted. This requires the prefix to be evaluated, which is attempted unless it involves an explicit function call (implicit function calls involving the use of `[`, `$`, etc *do not* inhibit evaluation).

Valid completions after the `$` extractor are determined by the generic function `.DollarNames`. Some basic methods are provided, and more can be written for custom classes.

**Completion inside namespaces:** When the `ns` setting is turned on, completion inside namespaces is attempted when a token is preceded by the `::` or `:::` operators. Additionally, the basic completion mechanism is extended to include all loaded namespaces, i.e., `foopkg::` becomes a valid completion of `foo` if `"foopkg"` is a loaded namespace.

The completion of package namespaces applies only to already loaded namespaces, i.e. if `MASS` is not loaded, `MAS` will not complete to `MASS::`. However, attempted completion *inside*

an apparent namespace will attempt to load the namespace if it is not already loaded, e.g. trying to complete on `MASS::fr` will load `MASS` if it is not already loaded.

**Completion for help items:** When the `help` setting is turned on, completion on help topics is attempted when a token is preceded by `?`. Prefixes (such as `class`, `method`) are supported, as well as quoted help topics containing special characters.

**Completion of function arguments:** When the `args` setting is turned on, completion on function arguments is attempted whenever deemed appropriate. The mechanism used will currently fail if the relevant function (at the point where completion is requested) was entered on a previous prompt (which implies in particular that the current line is being typed in response to a continuation prompt, usually `+`). Note that separation by newlines is fine.

The list of possible argument completions that is generated can be misleading. There is no problem for non-generic functions (except that `...` is listed as a completion; this is intentional as it signals the fact that the function can accept further arguments). However, for generic functions, it is practically impossible to give a reliable argument list without evaluating arguments (and not even then, in some cases), which is risky (in addition to being difficult to code, which is the real reason it hasn't even been tried), especially when that argument is itself an inline function call. Our compromise is to consider arguments of *all* currently available methods of that generic. This has two drawbacks. First, not all listed completions may be appropriate in the call currently being constructed. Second, for generics with many methods (like `print` and `plot`), many matches will need to be considered, which may take a noticeable amount of time. Despite these drawbacks, we believe this behaviour to be more useful than the only other practical alternative, which is to list arguments of the generic only.

Only S3 methods are currently supported in this fashion, and that can be turned off using the `S3` setting.

Since arguments can be unnamed in R function calls, other types of completion are also appropriate whenever argument completion is. Since there are usually many more visible objects than formal arguments of any particular function, possible argument completions are often buried in a bunch of other possibilities. However, recall that basic completion is suppressed for blank tokens. This can be useful to list possible arguments of a function. For example, trying to complete `seq([TAB])` and `seq(from = 1, [TAB])` will both list only the arguments of `seq` (or any of its methods), whereas trying to complete `seq(length[TAB])` will list both the `length.out` argument and the `length()` function as possible completions. Note that no attempt is made to remove arguments already supplied, as that would incur a further speed penalty.

**Special functions:** For a few special functions (`library`, `data`, etc), the first argument is treated specially, in the sense that normal completion is suppressed, and some function specific completions are enabled if so requested by the settings. The `ipck` setting, which controls whether `library` and `require` will complete on *installed packages*, is disabled by default because the first call to `installed.packages` is potentially time consuming (e.g., when packages are installed on a remote network file server). Note, however, that the results of a call to `installed.packages` is cached, so subsequent calls are usually fast, so turning this option on is not particularly onerous even in such situations.

## Value

If `rc.settings` is called without any arguments, it returns the current settings as a named logical vector. Otherwise, it returns `NULL` invisibly.

`rc.status` returns, as a list, the contents of an internal (unexported) environment that is used to record the results of the last completion attempt. This can be useful for debugging. For such use, one must resist the temptation to use completion when typing the call to `rc.status` itself, as that then becomes the last attempt by the time the call is executed.

The items of primary interest in the returned list are:

|                         |                                                                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>comps</code>      | The possible completions generated by the last call to <code>.completeToken</code> , as a character vector.                                                      |
| <code>token</code>      | The token that was (or, is to be) completed, as set by the last call to <code>.assignToken</code> (possibly inside a call to <code>.guessTokenFromLine</code> ). |
| <code>linebuffer</code> | The full line, as set by the last call to <code>.assignLinebuffer</code> .                                                                                       |
| <code>start</code>      | The start position of the token in the line buffer, as set by the last call to <code>.assignStart</code> .                                                       |
| <code>end</code>        | The end position of the token in the line buffer, as set by the last call to <code>.assignEnd</code> .                                                           |
| <code>fileName</code>   | Logical, indicating whether the cursor is currently inside quotes.                                                                                               |
| <code>fguess</code>     | The name of the function the cursor is currently inside.                                                                                                         |
| <code>isFirstArg</code> | Logical. If cursor is inside a function, is it the first argument?                                                                                               |

In addition, the components `settings` and `options` give the current values of settings and options respectively.

`rc.getOption` and `rc.options` behave much like [getOption](#) and [options](#) respectively.

## Unexported API

There are several unexported functions in the package. Of these, a few are special because they provide the API through which other mechanisms can make use of the facilities provided by this package (they are unexported because they are not meant to be called directly by users). The usage of these functions are:

```
.assignToken(text)
.assignLinebuffer(line)
.assignStart(start)
.assignEnd(end)

.completeToken()
.retrieveCompletions()
.getFileComp()

.guessTokenFromLine()
.win32consoleCompletion(linebuffer, cursorPosition,
                        check.repeat = TRUE,
                        minlength = -1)

.addFunctionInfo(...)
```

The first four functions set up a completion attempt by specifying the token to be completed (`text`), and indicating where (`start` and `end`, which should be integers) the token is placed within the complete line typed so far (`line`).

Potential completions of the token are generated by `.completeToken`, and the completions can be retrieved as an R character vector using `.retrieveCompletions`. It is possible for the user to specify a replacement for this function by setting `rc.options("custom.completer")`; if not NULL, this function is called to compute potential completions. This facility is meant to help in situations where completing as R code is not appropriate. See source code for more details.

If the cursor is inside quotes, completion may be suppressed. The function `.getFileComp` can be used after a call to `.completeToken` to determine if this is the case (returns TRUE), and alternative completions generated as deemed useful. In most cases, filename completion is a reasonable fallback.

The `.guessTokenFromLine` function is provided for use with backends that do not already break a line into tokens. It requires the `linebuffer` and `endpoint` (cursor position) to be already set, and itself sets the token and the start position. It returns the token as a character string.

The `.win32consoleCompletion` is similar in spirit, but is more geared towards the Windows GUI (or rather, any front-end that has no completion facilities of its own). It requires the `linebuffer` and cursor position as arguments, and returns a list with three components, `addition`, `possible` and `comps`. If there is an unambiguous extension at the current position, `addition` contains the additional text that should be inserted at the cursor. If there is more than one possibility, these are available either as a character vector of preformatted strings in `possible`, or as a single string in `comps`. `possible` consists of lines formatted using the current `width` option, so that printing them on the console one line at a time will be a reasonable way to list them. `comps` is a space separated (collapsed) list of the same completions, in case the front-end wishes to display it in some other fashion.

The `minlength` argument can be used to suppress completion when the token is too short (which can be useful if the front-end is set up to try completion on every keypress). If `check.repeat` is TRUE, it is detected if the same completion is being requested more than once in a row, and ambiguous completions are returned only in that case. This is an attempt to emulate GNU Readline behaviour, where a single TAB completes up to any unambiguous part, and multiple possibilities are reported only on two consecutive TABs.

As the various front-end interfaces evolve, the details of these functions are likely to change as well.

The function `.addFunctionInfo` can be used to add information about the permitted argument names for specific functions. Multiple named arguments are allowed in calls to it, where the tags are names of functions and values are character vectors representing valid arguments. When the `argdb` setting is TRUE, these are used as a source of valid argument names for the relevant functions.

## Note

If you are uncomfortable with unsolicited evaluation of pieces of code, you should set `ops = FALSE`. Otherwise, trying to complete `foo@ba` will evaluate `foo`, trying to complete `foo[i, 1:10]$ba` will evaluate `foo[i, 1:10]`, etc. This should not be too bad, as explicit function calls (involving parentheses) are not evaluated in this manner. However, this *will* affect promises and lazy loaded symbols.

read.DIF

*Data Input from Spreadsheet*

---

**Description**

Reads a file in Data Interchange Format (DIF) and creates a data frame from it. DIF is a format for data matrices such as single spreadsheets.

**Usage**

```
read.DIF(file, header = FALSE,
         dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"),
         row.names, col.names, as.is = !stringsAsFactors,
         na.strings = "NA", colClasses = NA, nrow = -1,
         skip = 0, check.names = TRUE, blank.lines.skip = TRUE,
         stringsAsFactors = default.stringsAsFactors(),
         transpose = FALSE, fileEncoding = "")
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file      | the name of the file which the data are to be read from, or a <a href="#">connection</a> , or a complete URL.<br>The name "clipboard" may also be used on Windows, in which case read.DIF("clipboard") will look for a DIF format entry in the Windows clipboard.                                                                                                                                                                                                                                            |
| header    | a logical value indicating whether the spreadsheet contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains only character values and the top left cell is empty.                                                                                                                                                                                                                        |
| dec       | the character used in the file for decimal points.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| numerals  | string indicating how to convert numbers whose conversion to double precision would lose accuracy, see <a href="#">type.convert</a> .                                                                                                                                                                                                                                                                                                                                                                        |
| row.names | a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names.<br>If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if row.names is missing, the rows are numbered.<br>Using row.names = NULL forces row numbering. |
| col.names | a vector of optional names for the variables. The default is to use "V" followed by the column number.                                                                                                                                                                                                                                                                                                                                                                                                       |

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| as.is            | <p>the default behavior of read.DIF is to convert character variables to factors. The variable as.is controls the conversion of columns not otherwise specified by colClasses. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.</p> <p>Note: In releases prior to R 2.12.1, cells marked as being of character type were converted to logical, numeric or complex using <a href="#">type.convert</a> as in <a href="#">read.table</a>.</p> <p>Note: to suppress all conversions including those of numeric columns, set colClasses = "character".</p> <p>Note that as.is is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.</p> |
| na.strings       | a character vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| colClasses       | <p>character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be NA.</p> <p>Possible values are NA (when <a href="#">type.convert</a> is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an as method (from package <b>methods</b>) for conversion from "character" to the specified formal class.</p> <p>Note that colClasses is specified per column (not per variable) and so includes the column of row names (if any).</p>                                                                                                                                                                 |
| nrows            | the maximum number of rows to read in. Negative values are ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| skip             | the number of lines of the data file to skip before beginning to read data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| check.names      | logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by <a href="#">make.names</a> ) so that they are, and also to ensure that there are no duplicates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| blank.lines.skip | logical: if TRUE blank lines in the input are ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| stringsAsFactors | logical: should character vectors be converted to factors?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| transpose        | logical, indicating if the row and column interpretation should be transposed. Microsoft's Excel has been known to produce (non-standard conforming) DIF files which would need transpose = TRUE to be read correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| fileEncoding     | character string: if non-empty declares the encoding used on a file (not a connection or clipboard) so the character data can be re-encoded. See the 'Encoding' section of the help for <a href="#">file</a> , the 'R Data Import/Export Manual' and 'Note'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Value

A data frame ([data.frame](#)) containing a representation of the data in the file. Empty input is an error unless col.names is specified, when a 0-row data frame is returned: similarly giving just a header line if header = TRUE results in a 0-row data frame.

**Note**

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).  
 Less memory will be used if `colClasses` is specified as one of the six atomic vector classes.

**Author(s)**

R Core; transpose option by Christoph Buser, ETH Zurich

**References**

The DIF format specification can be found by searching on <http://www.wotsit.org/>; the optional header fields are ignored. See also [https://en.wikipedia.org/wiki/Data\\_Interchange\\_Format](https://en.wikipedia.org/wiki/Data_Interchange_Format).

The term is likely to lead to confusion: Windows will have a ‘Windows Data Interchange Format (DIF) data format’ as part of its WinFX system, which may or may not be compatible.

**See Also**

The *R Data Import/Export* manual.

`scan`, `type.convert`, `read.fwf` for reading fixed width formatted input; `read.table`; `data.frame`.

**Examples**

```
## read.DIF() may need transpose = TRUE for a file exported from Excel
udir <- system.file("misc", package = "utils")
dd <- read.DIF(file.path(udir, "exDIF.dif"), header = TRUE, transpose = TRUE)
dc <- read.csv(file.path(udir, "exDIF.csv"), header = TRUE)
stopifnot(identical(dd, dc), dim(dd) == c(4,2))
```

---

read.fortran

---

*Read Fixed-Format Data in a Fortran-like Style*

---

**Description**

Read fixed-format data files using Fortran-style format specifications.

**Usage**

```
read.fortran(file, format, ..., as.is = TRUE, colClasses = NA)
```

**Arguments**

|                         |                                                                                    |
|-------------------------|------------------------------------------------------------------------------------|
| <code>file</code>       | File or <a href="#">connection</a> to read from.                                   |
| <code>format</code>     | Character vector or list of vectors. See ‘Details’ below.                          |
| <code>...</code>        | Other arguments for <a href="#">read.fwf</a> .                                     |
| <code>as.is</code>      | Keep characters as characters?                                                     |
| <code>colClasses</code> | Variable classes to override defaults. See <a href="#">read.table</a> for details. |

## Details

The format for a field is of one of the following forms: `rF1.d`, `rD1.d`, `rX1`, `rA1`, `rI1`, where `1` is the number of columns, `d` is the number of decimal places, and `r` is the number of repeats. `F` and `D` are numeric formats, `A` is character, `I` is integer, and `X` indicates columns to be skipped. The repeat code `r` and decimal place code `d` are always optional. The length code `1` is required except for `X` formats when `r` is present.

For a single-line record, format should be a character vector. For a multiline record it should be a list with a character vector for each line.

Skipped (`X`) columns are not passed to `read.fwf`, so `colClasses`, `col.names`, and similar arguments passed to `read.fwf` should not reference these columns.

## Value

A data frame

## Note

`read.fortran` does not use actual Fortran input routines, so the formats are at best rough approximations to the Fortran ones. In particular, specifying `d > 0` in the `F` or `D` format will shift the decimal `d` places to the left, even if it is explicitly specified in the input file.

## Examples

```
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fortran(ff, c("F2.1", "F2.0", "I2"))
read.fortran(ff, c("2F1.0", "2X", "2A1"))
unlink(ff)
cat(file = ff, "123456AB", "987654CD", sep = "\n")
read.fortran(ff, list(c("2F3.1", "A2"), c("3I2", "2X")))
unlink(ff)
# Note that the first number is read differently than Fortran would
# read it:
cat(file = ff, "12.3456", "1234567", sep = "\n")
read.fortran(ff, "F7.4")
unlink(ff)
```

---

read.fwf

*Read Fixed Width Format Files*

---

## Description

Read a table of **fixed width** formatted data into a [data.frame](#).

**Usage**

```
read.fwf(file, widths, header = FALSE, sep = "\t",
         skip = 0, row.names, col.names, n = -1,
         buffersize = 2000, fileEncoding = "", ...)
```

**Arguments**

|                           |                                                                                                                                                                                                                                                 |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>         | the name of the file which the data are to be read from.<br>Alternatively, <code>file</code> can be a <a href="#">connection</a> , which will be opened if necessary, and if so closed at the end of the function call.                         |
| <code>widths</code>       | integer vector, giving the widths of the fixed-width fields (of one line), or list of integer vectors giving widths for multiline records.                                                                                                      |
| <code>header</code>       | a logical value indicating whether the file contains the names of the variables as its first line. If present, the names must be delimited by <code>sep</code> .                                                                                |
| <code>sep</code>          | character; the separator used internally; should be a character that does not occur in the file (except in the header).                                                                                                                         |
| <code>skip</code>         | number of initial lines to skip; see <a href="#">read.table</a> .                                                                                                                                                                               |
| <code>row.names</code>    | see <a href="#">read.table</a> .                                                                                                                                                                                                                |
| <code>col.names</code>    | see <a href="#">read.table</a> .                                                                                                                                                                                                                |
| <code>n</code>            | the maximum number of records (lines) to be read, defaulting to no limit.                                                                                                                                                                       |
| <code>buffersize</code>   | Maximum number of lines to read at one time                                                                                                                                                                                                     |
| <code>fileEncoding</code> | character string: if non-empty declares the encoding used on a file (not a connection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for <a href="#">file</a> , the ‘R Data Import/Export Manual’ and ‘Note’. |
| <code>...</code>          | further arguments to be passed to <a href="#">read.table</a> . Useful such arguments include <code>as.is</code> , <code>na.strings</code> , <code>colClasses</code> and <code>strip.white</code> .                                              |

**Details**

Multiline records are concatenated to a single line before processing. Fields that are of zero-width or are wholly beyond the end of the line in `file` are replaced by NA.

Negative-width fields are used to indicate columns to be skipped, e.g., -5 to skip 5 columns. These fields are not seen by `read.table` and so should not be included in a `col.names` or `colClasses` argument (nor in the header line, if present).

Reducing the `buffersize` argument may reduce memory use when reading large files with long lines. Increasing `buffersize` may result in faster processing when enough memory is available.

Note that `read.fwf` (not `read.table`) reads the supplied file, so the latter’s argument `encoding` will not be useful.

**Value**

A [data.frame](#) as produced by [read.table](#) which is called internally.

**Author(s)**

Brian Ripley for R version: originally in Perl by Kurt Hornik.

**See Also**

[scan](#) and [read.table](#).

[read.fortran](#) for another style of fixed-format files.

**Examples**

```
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = c(1,2,3))    #> 1 23 456 \ 9 87 654
read.fwf(ff, widths = c(1,-2,3))   #> 1 456 \ 9 654
unlink(ff)
cat(file = ff, "123", "987654", sep = "\n")
read.fwf(ff, widths = c(1,0, 2,3))  #> 1 NA 23 NA \ 9 NA 87 654
unlink(ff)
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = list(c(1,0, 2,3), c(2,2,2))) #> 1 NA 23 456 98 76 54
unlink(ff)
```

---

read.socket

*Read from or Write to a Socket*

---

**Description**

`read.socket` reads a string from the specified socket, `write.socket` writes to the specified socket. There is very little error checking done by either.

**Usage**

```
read.socket(socket, maxlen = 256L, loop = FALSE)
write.socket(socket, string)
```

**Arguments**

|                     |                                              |
|---------------------|----------------------------------------------|
| <code>socket</code> | a socket object.                             |
| <code>maxlen</code> | maximum length (in bytes) of string to read. |
| <code>loop</code>   | wait for ever if there is nothing to read?   |
| <code>string</code> | string to write to socket.                   |

**Value**

`read.socket` returns the string read as a length-one character vector.  
`write.socket` returns the number of bytes written.

**Author(s)**

Thomas Lumley

```

finger <- function(user, host = "localhost", port = 79, print = TRUE)
{
  if (!is.character(user))
    stop("user name must be a string")
  user <- paste(user, "\r\n")
  socket <- make.socket(host, port)
  on.exit(close.socket(socket))
  write.socket(socket, user)
  output <- character(0)
  repeat{
    ss <- read.socket(socket)
    if (ss == "") break
    output <- paste(output, ss)
  }
  close.socket(socket)
  if (print) cat(output)
  invisible(output)
}
## Not run:
finger("root") ## only works if your site provides a finger daemon
## End(Not run)

```

read.table

*Data Input***Description**

Reads a file in table format and creates a data frame from it, with cases corresponding to lines and variables to fields in the file.

**Usage**

```

read.table(file, header = FALSE, sep = "", quote = "\"'",
  dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"),
  row.names, col.names, as.is = !stringsAsFactors,
  na.strings = "NA", colClasses = NA, nrow = -1,
  skip = 0, check.names = TRUE, fill = !blank.lines.skip,
  strip.white = FALSE, blank.lines.skip = TRUE,
  comment.char = "#",
  allowEscapes = FALSE, flush = FALSE,

```

```

stringsAsFactors = default.stringsAsFactors(),
fileEncoding = "", encoding = "unknown", text, skipNul = FALSE)

read.csv(file, header = TRUE, sep = ",", quote = "\"",
dec = ".", fill = TRUE, comment.char = "", ...)

read.csv2(file, header = TRUE, sep = ";", quote = "\"",
dec = ",", fill = TRUE, comment.char = "", ...)

read.delim(file, header = TRUE, sep = "\t", quote = "\"",
dec = ".", fill = TRUE, comment.char = "", ...)

read.delim2(file, header = TRUE, sep = "\t", quote = "\"",
dec = ",", fill = TRUE, comment.char = "", ...)

```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file      | <p>the name of the file which the data are to be read from. Each row of the table appears as one line of the file. If it does not contain an <i>absolute</i> path, the file name is <i>relative</i> to the current working directory, <code>getwd()</code>. Tilde-expansion is performed where supported. This can be a compressed file (see <a href="#">file</a>).</p> <p>Alternatively, file can be a readable text-mode <a href="#">connection</a> (which will be opened for reading if necessary, and if so <a href="#">closed</a> (and hence destroyed) at the end of the function call). (If <code>stdin()</code> is used, the prompts for lines may be somewhat confusing. Terminate input with a blank line or an EOF signal, Ctrl-D on Unix and Ctrl-Z on Windows. Any pushback on <code>stdin()</code> will be cleared before return.)</p> <p>file can also be a complete URL. (For the supported URL schemes, see the ‘URLs’ section of the help for <a href="#">url</a>.)</p> |
| header    | a logical value indicating whether the file contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains one fewer field than the number of columns.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| sep       | the field separator character. Values on each line of the file are separated by this character. If <code>sep = ""</code> (the default for <code>read.table</code> ) the separator is ‘white space’, that is one or more spaces, tabs, newlines or carriage returns.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| quote     | the set of quoting characters. To disable quoting altogether, use <code>quote = ""</code> . See <a href="#">scan</a> for the behaviour on quotes embedded in quotes. Quoting is only considered for columns read as character, which is all of them unless <code>colClasses</code> is specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| dec       | the character used in the file for decimal points.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| numerals  | string indicating how to convert numbers whose conversion to double precision would lose accuracy, see <a href="#">type.convert</a> . Can be abbreviated. (Applies also to complex-number inputs.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| row.names | a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | <p>If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if row.names is missing, the rows are numbered.</p> <p>Using row.names = NULL forces row numbering. Missing or NULL row.names generate row names that are considered to be ‘automatic’ (and not preserved by <a href="#">as.matrix</a>).</p>                                                                                                                                                                                                                                                                                                                         |
| col.names   | a vector of optional names for the variables. The default is to use "V" followed by the column number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| as.is       | <p>the default behavior of read.table is to convert character variables (which are not converted to logical, numeric or complex) to factors. The variable as.is controls the conversion of columns not otherwise specified by colClasses. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.</p> <p>Note: to suppress all conversions including those of numeric columns, set colClasses = "character".</p> <p>Note that as.is is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.</p>                                    |
| na.strings  | a character vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| colClasses  | <p>character. A vector of classes to be assumed for the columns. Recycled as necessary. If named and shorter than required, names are matched to the column names with unspecified values are taken to be NA.</p> <p>Possible values are NA (the default, when <a href="#">type.convert</a> is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an as method (from package <b>methods</b>) for conversion from "character" to the specified formal class.</p> <p>Note that colClasses is specified per column (not per variable) and so includes the column of row names (if any).</p> |
| nrows       | integer: the maximum number of rows to read in. Negative and other invalid values are ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| skip        | integer: the number of lines of the data file to skip before beginning to read data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| check.names | logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by <a href="#">make.names</a> ) so that they are, and also to ensure that there are no duplicates.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| fill        | logical. If TRUE then in case the rows have unequal length, blank fields are implicitly added. See ‘Details’.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| strip.white | logical. Used only when sep has been specified, and allows the stripping of leading and trailing white space from unquoted character fields (numeric fields are always stripped). See <a href="#">scan</a> for further details (including the exact meaning of ‘white space’), remembering that the columns may include the row names.                                                                                                                                                                                                                                                                                                                                                                                                 |

|                               |                                                                                                                                                                                                                                                                                                          |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>blank.lines.skip</code> | logical: if TRUE blank lines in the input are ignored.                                                                                                                                                                                                                                                   |
| <code>comment.char</code>     | character: a character vector of length one containing a single character or an empty string. Use "" to turn off the interpretation of comments altogether.                                                                                                                                              |
| <code>allowEscapes</code>     | logical. Should C-style escapes such as ‘\n’ be processed or read verbatim (the default)? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character). For more details see <a href="#">scan</a> .                                                         |
| <code>flush</code>            | logical: if TRUE, scan will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field.                                                                                                                                              |
| <code>stringsAsFactors</code> | logical: should character vectors be converted to factors? Note that this is overridden by <code>as.is</code> and <code>colClasses</code> , both of which allow finer control.                                                                                                                           |
| <code>fileEncoding</code>     | character string: if non-empty declares the encoding used on a file (not a connection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for <a href="#">file</a> , the ‘R Data Import/Export Manual’ and ‘Note’.                                                          |
| <code>encoding</code>         | encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8 (see <a href="#">Encoding</a> ): it is not used to re-encode the input, but allows R to handle encoded strings in their native encoding (if one of those two). See ‘Value’ and ‘Note’. |
| <code>text</code>             | character string: if file is not supplied and this is, then data are read from the value of <code>text</code> via a text connection. Notice that a literal string can be used to include (small) data sets within R code.                                                                                |
| <code>skipNul</code>          | logical: should nuls be skipped?                                                                                                                                                                                                                                                                         |
| <code>...</code>              | Further arguments to be passed to <code>read.table</code> .                                                                                                                                                                                                                                              |

## Details

This function is the principal means of reading tabular data into R.

Unless `colClasses` is specified, all columns are read as character columns and then converted using [type.convert](#) to logical, integer, numeric, complex or (depending on `as.is`) factor as appropriate. Quotes are (by default) interpreted in all fields, so a column of values like "42" will result in an integer column.

A field or line is ‘blank’ if it contains nothing (except whitespace if no separator is specified) before a comment character or the end of the field or line.

If `row.names` is not specified and the header line has one less entry than the number of columns, the first column is taken to be the row names. This allows data frames to be read in from the format in which they are printed. If `row.names` is specified and does not refer to the first column, that column is discarded from such files.

The number of data columns is determined by looking at the first five lines of input (or the whole input if it has less than five lines), or from the length of `col.names` if it is specified and is longer. This could conceivably be wrong if `fill` or `blank.lines.skip` are true, so specify `col.names` if necessary (as in the ‘Examples’).

`read.csv` and `read.csv2` are identical to `read.table` except for the defaults. They are intended for reading ‘comma separated value’ files (‘.csv’) or (`read.csv2`) the variant used in countries that use a comma as decimal point and a semicolon as field separator. Similarly, `read.delim`

and `read.delim2` are for reading delimited files, defaulting to the TAB character for the delimiter. Notice that `header = TRUE` and `fill = TRUE` in these variants, and that the comment character is disabled.

The rest of the line after a comment character is skipped; quotes are not processed in comments. Complete comment lines are allowed provided `blank.lines.skip = TRUE`; however, comment lines prior to the header must have the comment character in the first non-blank column.

Quoted fields with embedded newlines are supported except after a comment character. Embedded nuls are unsupported: skipping them (with `skipNul = TRUE`) may work.

### Value

A data frame ([data.frame](#)) containing a representation of the data in the file.

Empty input is an error unless `col.names` is specified, when a 0-row data frame is returned: similarly giving just a header line if `header = TRUE` results in a 0-row data frame. Note that in either case the columns will be logical unless `colClasses` was supplied.

Character strings in the result (including factor levels) will have a declared encoding if encoding is "latin1" or "UTF-8".

### Memory usage

These functions can use a surprising amount of memory when reading large files. There is extensive discussion in the 'R Data Import/Export' manual, supplementing the notes here.

Less memory will be used if `colClasses` is specified as one of the six [atomic](#) vector classes. This can be particularly so when reading a column that takes many distinct numeric values, as storing each distinct value as a character string can take up to 14 times as much memory as storing it as an integer.

Using `nrows`, even as a mild over-estimate, will help memory usage.

Using `comment.char = ""` will be appreciably faster than the `read.table` default.

`read.table` is not the right tool for reading large matrices, especially those with many columns: it is designed to read *data frames* which may have columns of very different classes. Use [scan](#) instead for matrices.

### Note

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).

There are two approaches for reading input that is not in the local encoding. If the input is known to be UTF-8 or Latin1, use the encoding argument to declare that. If the input is in some other encoding, then it may be translated on input. The `fileEncoding` argument achieves this by setting up a connection to do the re-encoding into the current locale. Note that on Windows or other systems not running in a UTF-8 locale, this may not be possible.

`scan`, `type.convert`, `read.fwf` for reading *fixed width formatted* input; `write.table`; `data.frame`.

`count.fields` can be useful to determine problems with reading files which result in reports of incorrect record lengths (see the ‘Examples’ below).

<https://tools.ietf.org/html/rfc4180> for the IANA definition of CSV files (which requires comma as separator and CRLF line endings).

## Examples

```
## using count.fields to handle unknown maximum number of fields
## when fill = TRUE
test1 <- c(1:5, "6,7", "8,9,10")
tf <- tempfile()
writeLines(test1, tf)

read.csv(tf, fill = TRUE) # 1 column
ncol <- max(count.fields(tf, sep = ","))
read.csv(tf, fill = TRUE, header = FALSE,
         col.names = paste0("V", seq_len(ncol)))
unlink(tf)

## "Inline" data set, using text=
## Notice that leading and trailing empty lines are auto-trimmed

read.table(header = TRUE, text = "
a b
1 2
3 4
")
```

---

recover

*Browsing after an Error*

---

## Description

This function allows the user to browse directly on any of the currently active function calls, and is suitable as an error option. The expression `options(error = recover)` will make this the error option.

## Usage

```
recover()
```

## Details

When called, `recover` prints the list of current calls, and prompts the user to select one of them. The standard R [browser](#) is then invoked from the corresponding environment; the user can type ordinary R language expressions to be evaluated in that environment.

When finished browsing in this call, type `c` to return to `recover` from the browser. Type another frame number to browse some more, or type `0` to exit `recover`.

The use of `recover` largely supersedes [dump.frames](#) as an error option, unless you really want to wait to look at the error. If `recover` is called in non-interactive mode, it behaves like `dump.frames`. For computations involving large amounts of data, `recover` has the advantage that it does not need to copy out all the environments in order to browse in them. If you do decide to quit interactive debugging, call [dump.frames](#) directly while browsing in any frame (see the examples).

## Value

Nothing useful is returned. However, you *can* invoke `recover` directly from a function, rather than through the error option shown in the examples. In this case, execution continues after you type `0` to exit `recover`.

## Compatibility Note

The R `recover` function can be used in the same way as the S function of the same name; therefore, the error option shown is a compatible way to specify the error action. However, the actual functions are essentially unrelated and interact quite differently with the user. The navigating commands `up` and `down` do not exist in the R version; instead, exit the browser and select another frame.

## References

John M. Chambers (1998). *Programming with Data*; Springer.  
See the compatibility note above, however.

## See Also

Browse[1]> dump.frames() # save for offline debugging
Browse[1]> c # exit the browser

Enter a frame number, or 0 to exit
1:lm(y ~ x, data = xy, weights = w)
2:lm.wfit(x, y, w, offset = offset, ...)
Selection: 0 # exit recover
>

```

```
## End(Not run)
```

---

relist

---

*Allow Re-Listing an unlist()ed Object*

---

## Description

`relist()` is an S3 generic function with a few methods in order to allow easy inversion of `unlist(obj)` when that is used with an object `obj` of (S3) class "relistable".

## Usage

```

relist(flesh, skeleton)
## Default S3 method:
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'factor'
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'list'
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'matrix'
relist(flesh, skeleton = attr(flesh, "skeleton"))

as.relistable(x)
is.relistable(x)

## S3 method for class 'relistable'
unlist(x, recursive = TRUE, use.names = TRUE)

```

## Arguments

|           |                                                                       |
|-----------|-----------------------------------------------------------------------|
| flesh     | a vector to be relisted                                               |
| skeleton  | a list, the structure of which determines the structure of the result |
| x         | an R object, typically a list (or vector).                            |
| recursive | logical. Should unlisting be applied to list components of x?         |
| use.names | logical. Should names be preserved?                                   |

## Details

Some functions need many parameters, which are most easily represented in complex structures, e.g., nested lists. Unfortunately, many mathematical functions in R, including `optim` and `nlm` can only operate on functions whose domain is a vector. R has `unlist()` to convert nested list objects into a vector representation. `relist()`, its methods and the functionality mentioned here provide the inverse operation to convert vectors back to the convenient structural representation. This allows structured functions (such as `optim()`) to have simple mathematical interfaces.

For example, a likelihood function for a multivariate normal model needs a variance-covariance matrix and a mean vector. It would be most convenient to represent it as a list containing a vector and a matrix. A typical parameter might look like

```
list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0))).
```

However, `optim` cannot operate on functions that take lists as input; it only likes numeric vectors. The solution is conversion. Given a function `mvdnorm(x, mean, vcov, log = FALSE)` which computes the required probability density, then

```
ipar <- list(mean = c(0, 1), vcov = c bind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)

ll <- function(param.vector)
{
  param <- relist(param.vector, skeleton = ipar)
  -sum(mvdnorm(x, mean = param$mean, vcov = param$vcov,
              log = TRUE))
}

optim(unlist(initial.param), ll)
```

`relist` takes two parameters: `skeleton` and `flesh`. `Skeleton` is a sample object that has the right shape but the wrong content. `flesh` is a vector with the right content but the wrong shape. Invoking

```
relist(flesh, skeleton)
```

will put the content of `flesh` on the `skeleton`. You don't need to specify `skeleton` explicitly if the `skeleton` is stored as an attribute inside `flesh`. In particular, if `flesh` was created from some object `obj` with `unlist(as.relistable(obj))` then the `skeleton` attribute is automatically set. (Note that this does not apply to the example here, as `optim` is creating a new vector to pass to `ll` and not its `par` argument.)

As long as `skeleton` has the right shape, it should be a precise inverse of `unlist`. These equalities hold:

```
relist(unlist(x), x) == x
unlist(relist(y, skeleton)) == y
```

```
x <- as.relistable(x)
relist(unlist(x)) == x
```

**Value**

an object of (S3) class "relistable" (and "list").

**Author(s)**

R Core, based on a code proposal by Andrew Clausen.

**See Also**

[unlist](#)

**Examples**

```
ipar <- list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)
ul <- unlist(initial.param)
relist(ul)
stopifnot(identical(relist(ul), initial.param))
```

---

REMOVE

*Remove Add-on Packages*

---

**Description**

Utility for removing add-on packages.

**Usage**

```
R CMD REMOVE [options] [-l lib] pkgs
```

**Arguments**

|         |                                                                                                                             |
|---------|-----------------------------------------------------------------------------------------------------------------------------|
| pkgs    | a space-separated list with the names of the packages to be removed.                                                        |
| lib     | the path name of the R library tree to remove from. May be absolute or relative. Also accepted in the form '--library=lib'. |
| options | further options for help or version.                                                                                        |

### Details

If used as `R CMD REMOVE pkgs` without explicitly specifying `lib`, packages are removed from the library tree rooted at the first directory in the library path which would be used by `R` run in the current environment.

To remove from the library tree *lib* instead of the default one, use `R CMD REMOVE -l lib pkgs`.

Use `R CMD REMOVE --help` for more usage information.

### Note

Some binary distributions of `R` have `REMOVE` in a separate bundle, e.g. an `R-devel` RPM.

|------------------------------|----------------------------------|
| <code>remove.packages</code> | <i>Remove Installed Packages</i> |
|------------------------------|----------------------------------|

---

### Description

Removes installed packages/bundles and updates index information as necessary.

### Usage

```
remove.packages(pkgs, lib)
```

### Arguments

|                   |                                                                                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pkgs</code> | a character vector with the names of the packages to be removed.                                                                                          |
| <code>lib</code>  | a character vector giving the library directories to remove the packages from. If missing, defaults to the first element in <a href="#">.libPaths()</a> . |

### See Also

---

|              |                                              |
|--------------|----------------------------------------------|
| removeSource | <i>Remove Stored Source from a Function.</i> |
|--------------|----------------------------------------------|

---

**Description**

When `options("keep.source")` is TRUE, a copy of the original source code to a function is stored with it. This function removes that copy.

**Usage**

```
removeSource(fn)
```

**Arguments**

`fn`                      A single function from which to remove the source.

**Details**

This removes the "srcref" and related attributes.

**Value**

A copy of the function with the source removed.

**See Also**

[srcref](#) for a description of source reference records, [deparse](#) for a description of how functions are deparsed.

**Examples**

```
fn <- function(x) {  
  x + 1 # A comment, kept as part of the source  
}  
fn  
fn <- removeSource(fn)  
fn
```

---

|       |                         |
|-------|-------------------------|
| RHOME | <i>R Home Directory</i> |
|-------|-------------------------|

---

**Description**

Returns the location of the R home directory, which is the root of the installed R tree.

**Usage**

```
R RHOME
```

---

roman

*Roman Numerals*

---

## Description

Manipulate integers as roman numerals.

## Usage

```
as.roman(x)
```

## Arguments

x                    a numeric vector, or a character vector of arabic or roman numerals.

## Details

as.roman creates objects of class "roman" which are internally represented as integers, and have suitable methods for printing, formatting, subsetting, and coercion to character.

Only numbers between 1 and 3899 have a unique representation as roman numbers.

## References

Wikipedia contributors (2006). Roman numerals. Wikipedia, The Free Encyclopedia. [https://en.wikipedia.org/w/index.php?title=Roman\\_numerals&oldid=78252134](https://en.wikipedia.org/w/index.php?title=Roman_numerals&oldid=78252134). Accessed September 29, 2006.

## Examples

```
## First five roman 'numbers'.
(y <- as.roman(1 : 5))
## Middle one.
y[3]
## Current year as a roman number.
(y <- as.roman(format(Sys.Date(), "%Y")))
## 10 years ago ...
y - 10
```

---

Rprof*Enable Profiling of R's Execution*

---

## Description

Enable or disable profiling of the execution of R expressions.

## Usage

```
Rprof(filename = "Rprof.out", append = FALSE, interval = 0.02,  
       memory.profiling = FALSE, gc.profiling = FALSE,  
       line.profiling = FALSE, numfiles = 100L, bufsize = 10000L)
```

## Arguments

|                   |                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------|
| filename          | The file to be used for recording the profiling results. Set to NULL or "" to disable profiling. |
| append            | logical: should the file be over-written or appended to?                                         |
| interval          | real: time interval between samples.                                                             |
| memory.profiling  | logical: write memory use information to the file?                                               |
| gc.profiling      | logical: record whether GC is running?                                                           |
| line.profiling    | logical: write line locations to the file?                                                       |
| numfiles, bufsize | integers: line profiling memory allocation                                                       |

## Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling works by writing out the call stack every interval seconds, to the file specified. Either the [summaryRprof](#) function or the wrapper script `R CMD Rprof` can be used to process the output file to produce a summary of the usage; use `R CMD Rprof --help` for usage information.

How time is measured varies by platform: on a Unix-alike it is the CPU time of the R process, so for example excludes time when R is waiting for input or for processes run by [system](#) to return.

Note that the timing interval cannot usefully be too small: once the timer goes off, the information is not recorded until the next timing click (probably in the range 1–10msecs).

Functions will only be recorded in the profile log if they put a context on the call stack (see [sys.calls](#)). Some [primitive](#) functions do not do so: specifically those which are of [type](#) "special" (see the 'R Internals' manual for more details).

Individual statements will be recorded in the profile log if `line.profiling` is TRUE, and if the code being executed was parsed with source references. See [parse](#) for a discussion of source references. By default the statement locations are not shown in [summaryRprof](#), but see that help page for options to enable the display.

**Note**

Profiling is not available on all platforms. By default, support for profiling is compiled in if possible – configure R with ‘--disable-R-profiling’ to change this.

As R profiling uses the same mechanisms as C profiling, the two cannot be used together, so do not use Rprof in an executable built for C-level profiling.

**Note**

The profiler interrupts R asynchronously, and it cannot allocate memory to store results as it runs. This affects line profiling, which needs to store an unknown number of file pathnames. The `numfiles` and `bufsize` arguments control the size of pre-allocated buffers to hold these results: the former counts the maximum number of paths, the latter counts the numbers of bytes in them. If the profiler runs out of space it will skip recording the line information for new files, and issue a warning when `Rprof(NULL)` is called to finish profiling.

**See Also**

The chapter on “Tidying and profiling R code” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

[summaryRprof](#) to analyse the output file.

[tracemem](#), [Rprofmem](#) for other ways to track memory use.

**Examples**

```
## Not run: Rprof()
## some code to be profiled
Rprof(NULL)
## some code NOT to be profiled
Rprof(append = TRUE)
## some code to be profiled
Rprof(NULL)
...
## Now post-process the output as described in Details

## End(Not run)
```

---

Rprofmem

*Enable Profiling of R's Memory Use*

---

**Description**

Enable or disable reporting of memory allocation in R.

**Usage**

```
Rprofmem(filename = "Rprofmem.out", append = FALSE, threshold = 0)
```

**Arguments**

|           |                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------|
| filename  | The file to be used for recording the memory allocations. Set to NULL or "" to disable reporting.  |
| append    | logical: should the file be over-written or appended to?                                           |
| threshold | numeric: allocations on R's "large vector" heap larger than this number of bytes will be reported. |

**Details**

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling writes the call stack to the specified file every time malloc is called to allocate a large vector object or to allocate a page of memory for small objects. The size of a page of memory and the size above which malloc is used for vectors are compile-time constants, by default 2000 and 128 bytes respectively.

The profiler tracks allocations, some of which will be to previously used memory and will not increase the total memory use of R.

**Value**

None

**Note**

The memory profiler slows down R even when not in use, and so is a compile-time option. The memory profiler can be used at the same time as other R and C profilers.

**See Also**

The R sampling profiler, [Rprof](#) also collects memory information.

[tracemem](#) traces duplications of specific objects.

The "Writing R Extensions" manual section on "Tidying and profiling R code"

**Examples**

```
## Not run:
## not supported unless R is compiled to support it.
Rprofmem("Rprofmem.out", threshold = 1000)
example(glm)
Rprofmem(NULL)
noquote(readLines("Rprofmem.out", n = 5))

## End(Not run)
```

---

Rscript

---

*Scripting Front-End for R*

---

## Description

This is an alternative front end for use in ‘#!’ scripts and other scripting applications.

## Usage

```
Rscript [options] [-e expr [-e expr2 ...] | file] [args]
```

## Arguments

|             |                                                                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| options     | a list of options, all beginning with ‘--’. These can be any of the options of the standard R front-end, and also those described in the details. |
| expr, expr2 | R expression(s), properly quoted.                                                                                                                 |
| file        | the name of a file containing R commands. ‘-’ indicates ‘stdin’.                                                                                  |
| args        | arguments to be passed to the script in file.                                                                                                     |

## Details

Rscript --help gives details of usage, and Rscript --version gives the version of Rscript.

Other invocations invoke the R front-end with selected options. This front-end is convenient for writing ‘#!’ scripts since it is an executable and takes file directly as an argument. Options ‘--slave --no-restore’ are always supplied: these imply ‘--no-save’. (The standard Windows command line has no concept of ‘#!’ scripts, but Cygwin shells do.)

Either one or more ‘-e’ options or file should be supplied. When using ‘-e’ options be aware of the quoting rules in the shell used: see the examples.

Additional options accepted (before file or args) are

‘--verbose’ gives details of what Rscript is doing. Also passed on to R.

‘--default-packages=list’ where list is a comma-separated list of package names or NULL. Sets the environment variable R\_DEFAULT\_PACKAGES which determines the packages loaded on startup. The default for Rscript omits **methods** as it takes about 60% of the startup time.

Spaces are allowed in expression and file (but will need to be protected from the shell in use, if any, for example by enclosing the argument in quotes).

Normally the version of R is determined at installation, but this can be overridden by setting the environment variable RHOME.

`stdin()` refers to the input file, and `file("stdin")` to the stdin file stream of the process.

## Note

Rscript is only supported on systems with the execv system call.

## Examples

```
## Not run:
Rscript -e 'date()' -e 'format(Sys.time(), "%a %b %d %X %Y")'

## example #! script for a Unix-alike

#! /path/to/Rscript --vanilla --default-packages=utils
args <- commandArgs(TRUE)
res <- try(install.packages(args))
if(inherits(res, "try-error")) q(status=1) else q()

## End(Not run)
```

---

RShowDoc

*Show R Manuals and Other Documentation*

---

## Description

Utility function to find and display R documentation.

## Usage

```
RShowDoc(what, type = c("pdf", "html", "txt"), package)
```

## Arguments

|         |                                                                                                       |
|---------|-------------------------------------------------------------------------------------------------------|
| what    | a character string: see ‘Details’.                                                                    |
| type    | an optional character string giving the preferred format. Can be abbreviated.                         |
| package | an optional character string specifying the name of a package within which to look for documentation. |

## Details

what can specify one of several different sources of documentation, including the R manuals (R-admin, R-data, R-exts, R-intro, R-ints, R-lang), NEWS, COPYING (the GPL licence), any of the licenses in ‘share/licenses’, FAQ (also available as R-FAQ), and the files in ‘[R\\_HOME](#)/doc’.

Only on Windows, the R for Windows FAQ is specified by rw-FAQ.

If package is supplied, documentation is looked for in the ‘doc’ and top-level directories of an installed package of that name.

If what is missing a brief usage message is printed.

The documentation types are tried in turn starting with the first specified in type (or "pdf" if none is specified).

## Value

A invisible character string given the path to the file found.

**See Also**

For displaying regular help files, [help](#) (or [?](#)) and [help.start](#).

For type = "txt", [file.show](#) is used. [vignettes](#) are nicely viewed via `RShowDoc(*, package= . )`.

**Examples**

```
RShowDoc("R-lang")
RShowDoc("FAQ", type = "html")
RShowDoc("frame", package = "grid")
RShowDoc("changes.txt", package = "grid")
RShowDoc("NEWS", package = "MASS")
```

---

RSiteSearch

*Search for Key Words or Phrases in Documentation*

---

**Description**

Search for key words or phrases in help pages, vignettes or task views, using the search engine at <http://search.r-project.org> and view them in a web browser.

**Usage**

```
RSiteSearch(string,
            restrict = c("functions", "vignettes", "views"),
            format = c("normal", "short"),
            sortby = c("score", "date:late", "date:early",
                      "subject", "subject:descending",
                      "from", "from:descending",
                      "size", "size:descending"),
            matchesPerPage = 20)
```

**Arguments**

|                |                                                                                                                                                                                                                                                                                                                                                                         |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| string         | A character string specifying word(s) or a phrase to search. If the words are to be searched as one entity, enclose all words in braces (see the first example).                                                                                                                                                                                                        |
| restrict       | a character vector, typically of length greater than one. Values can be abbreviated. Possible areas to search in: functions for help pages, views for task views and vignettes for package vignettes.                                                                                                                                                                   |
| format         | normal or short (no excerpts); can be abbreviated.                                                                                                                                                                                                                                                                                                                      |
| sortby         | character string (can be abbreviated) indicating how to sort the search results: (score, date:late for sorting by date with latest results first, date:early for earliest first, subject for subject in alphabetical order, subject:descending for reverse alphabetical order, from or from:descending for sender (when applicable), size or size:descending for size.) |
| matchesPerPage | How many items to show per page.                                                                                                                                                                                                                                                                                                                                        |

## Details

This function is designed to work with the search site at <http://search.r-project.org>, and depends on that site continuing to be made available (thanks to Jonathan Baron and the School of Arts and Sciences of the University of Pennsylvania).

Unique partial matches will work for all arguments. Each new browser window will stay open unless you close it.

## Value

(Invisibly) the complete URL passed to the browser, including the query string.

## Author(s)

Andy Liaw and Jonathan Baron

## See Also

[help.search](#), [help.start](#) for local searches.

[browseURL](#) for how the help file is displayed.

## Examples

```
# need Internet connection
RSiteSearch("{logistic regression}") # matches exact phrase
Sys.sleep(5) # allow browser to open, take a quick look
## Search in vignettes and store the query-string:
fullquery <- RSiteSearch("lattice", restrict = "vignettes")
fullquery # a string of ~ 110 characters
```

---

rtags

*An Etags-like Tagging Utility for R*

---

## Description

rtags provides etags-like indexing capabilities for R code, using R's own parser.

## Usage

```
rtags(path = ".", pattern = "\\.[RrSs]$",
      recursive = FALSE,
      src = list.files(path = path, pattern = pattern,
                      full.names = TRUE,
                      recursive = recursive),
      keep.re = NULL,
      ofile = "", append = FALSE,
      verbose = getOption("verbose"))
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                      |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| path, pattern, recursive | Arguments passed on to <code>list.files</code> to determine the files to be tagged. By default, these are all files with extension <code>.R</code> , <code>.r</code> , <code>.S</code> , and <code>.s</code> in the current directory. These arguments are ignored if <code>src</code> is specified. |
| src                      | A vector of file names to be indexed.                                                                                                                                                                                                                                                                |
| keep.re                  | A regular expression further restricting <code>src</code> (the files to be indexed). For example, specifying <code>keep.re = "/R/[^/]*\\.R\$"</code> will only retain files with extension <code>.R</code> inside a directory named <code>R</code> .                                                 |
| ofile                    | Passed on to <code>cat</code> as the file argument; typically the output file where the tags will be written ("TAGS" by convention). By default, the output is written to the R console (unless redirected).                                                                                         |
| append                   | Logical, indicating whether the output should overwrite an existing file, or append to it.                                                                                                                                                                                                           |
| verbose                  | Logical. If TRUE, file names are echoed to the R console as they are processed.                                                                                                                                                                                                                      |

**Details**

Many text editors allow definitions of functions and other language objects to be quickly and easily located in source files through a tagging utility. This functionality requires the relevant source files to be preprocessed, producing an index (or tag) file containing the names and their corresponding locations. There are multiple tag file formats, the most popular being the vi-style `ctags` format and the emacs-style `etags` format. Tag files in these formats are usually generated by the `ctags` and `etags` utilities respectively. Unfortunately, these programs do not recognize R code syntax. They do allow tagging of arbitrary language files through regular expressions, but this too is insufficient.

The `rtags` function is intended to be a tagging utility for R code. It parses R code files (using R's parser) and produces tags in Emacs' `etags` format. Support for vi-style tags is currently absent, but should not be difficult to add.

**See Also**

`list.files`, `cat`

**Examples**

```
## Not run:
rtags("/path/to/src/repository",
      pattern = "[.]*\\.R[RsS]$",
```

```

    keep.re = "/R/",
    verbose = TRUE,
    ofile = "TAGS",
    append = FALSE,
    recursive = TRUE)

## End(Not run)

```

---

Rtangle

*R Driver for Stangle*

---

## Description

A driver for [Stangle](#) that extracts R code chunks.

## Usage

```

Rtangle()
RtangleSetup(file, syntax, output = NULL, annotate = TRUE,
             split = FALSE, quiet = FALSE, ...)

```

## Arguments

|                       |                                                                                                                                                                        |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>     | Name of Sweave source file. See the description of the corresponding argument of <a href="#">Sweave</a> .                                                              |
| <code>syntax</code>   | An object of class <code>SweaveSyntax</code> .                                                                                                                         |
| <code>output</code>   | Name of output file used unless <code>split = TRUE</code> : see ‘Details’.                                                                                             |
| <code>annotate</code> | By default, code chunks are separated by comment lines specifying the names and numbers of the code chunks. If <code>FALSE</code> the decorating comments are omitted. |
| <code>split</code>    | Split output into a file for each code chunk?                                                                                                                          |
| <code>quiet</code>    | If <code>TRUE</code> all progress messages are suppressed.                                                                                                             |
| <code>...</code>      | Additional named arguments setting defaults for further options.                                                                                                       |

## Details

Unless `split = TRUE`, the default name of the output file is `basename(file)` with an extension corresponding to the Sweave syntax (e.g., ‘`Rnw`’, ‘`Stex`’) replaced by ‘`R`’. File names “`stdout`” and “`stderr`” are interpreted as the output and message connection respectively.

If splitting is selected (including by the options in the file), each chunk is written to a separate file with extension the name of the ‘engine’ (default ‘`.R`’).

The annotation is of one of the forms

```
#####
### code chunk number 3: viewport
#####

#####
### code chunk number 18: grid.Rnw:647-648
#####

#####
### code chunk number 19: trellisdata (eval = FALSE)
#####
```

using either the chunk label or the file name and line numbers.

Note that this driver does not simply extract the code chunks verbatim because code chunks can re-use earlier chunks.

## Supported Options

Rtangle supports the following options for code chunks (the values in parentheses show the default values):

**engine:** character string ("R"). Only chunks with engine equal to "R" or "S" are processed.

**keep.source:** logical (TRUE). If `keep.source == TRUE` the original source is copied to the file. Otherwise, deparsed source is output.

**eval:** logical (TRUE). If FALSE, the code chunk is copied across but commented out.

**prefix** Used if `split = TRUE`. See `prefix.string`.

**prefix.string:** a character string, default is the name of the source file (without extension). Used if `split = TRUE` as the prefix for the filename if the chunk has no label, or if it has a label and `prefix = TRUE`. Note that this is used as part of filenames, so needs to be portable.

**show.line.nos** logical (FALSE). Should the output be annotated with comments showing the line number of the first code line of the chunk?

RweaveLatex

*R/LaTeX Driver for Sweave***Description**

A driver for [Sweave](#) that translates R code chunks in LaTeX files.

**Usage**

```
RweaveLatex()
```

```
RweaveLatexSetup(file, syntax, output = NULL, quiet = FALSE,
                  debug = FALSE, stylepath, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>      | Name of Sweave source file. See the description of the corresponding argument of <a href="#">Sweave</a> .                                                                                                                                                                                      |
| <code>syntax</code>    | An object of class <code>SweaveSyntax</code> .                                                                                                                                                                                                                                                 |
| <code>output</code>    | Name of output file. The default is to remove extension <code>‘.nw’</code> , <code>‘.Rnw’</code> or <code>‘.Snw’</code> and to add extension <code>‘.tex’</code> . Any directory paths in <code>file</code> are also removed such that the output is created in the current working directory. |
| <code>quiet</code>     | If TRUE all progress messages are suppressed.                                                                                                                                                                                                                                                  |
| <code>debug</code>     | If TRUE, input and output of all code chunks is copied to the console.                                                                                                                                                                                                                         |
| <code>stylepath</code> | See ‘Details’.                                                                                                                                                                                                                                                                                 |
| <code>...</code>       | named values for the options listed in ‘Supported Options’.                                                                                                                                                                                                                                    |

**Details**

The LaTeX file generated needs to contain the line `‘\usepackage{Sweave}’`, and if this is not present in the Sweave source file (possibly in a comment), it is inserted by the `RweaveLatex` driver. If `stylepath = TRUE`, a hard-coded path to the file `‘Sweave.sty’` in the R installation is set in place of `Sweave`. The hard-coded path makes the LaTeX file less portable, but avoids the problem of installing the current version of `‘Sweave.sty’` to some place in your TeX input path. However, TeX may not be able to process the hard-coded path if it contains spaces (as it often will under Windows) or TeX special characters.

The default for `stylepath` is now taken from the environment variable `SWEAVE_STYLEPATH_DEFAULT`, or is FALSE if that is unset or empty. If set, it should be exactly TRUE or FALSE: any other values are taken as FALSE.

The simplest way for frequent Sweave users to ensure that `‘Sweave.sty’` is in the TeX input path is to add `‘R_HOME/share/texmf’` as a ‘texmf tree’ (‘root directory’ in the parlance of the ‘MiKTeX settings’ utility).

By default, `‘Sweave.sty’` sets the width of all included graphics to:  
`‘\setkeys{Gin}{width=0.8\textwidth}’`.

This setting affects the width size option passed to the `\includegraphics{}` directive for each plot file and in turn impacts the scaling of your plot files as they will appear in your final document. Thus, for example, you may set `width=3` in your figure chunk and the generated graphics files will be set to 3 inches in width. However, the width of your graphic in your final document will be set to `0.8\textwidth` and the height dimension will be scaled accordingly. Fonts and symbols will be similarly scaled in the final document.

You can adjust the default value by including the `\setkeys{Gin}{width=...}` directive in your `.Rnw` file after the `\begin{document}` directive and changing the width option value as you prefer, using standard LaTeX measurement values.

If you wish to override this default behavior entirely, you can add a `\usepackage[nogin]{Sweave}` directive in your preamble. In this case, no size/scaling options will be passed to the `\includegraphics{}` directive and the height and width options will determine both the runtime generated graphic file sizes and the size of the graphics in your final document.

`Sweave.sty` also supports the `[noae]` option, which suppresses the use of the `ae` package, the use of which may interfere with certain encoding and typeface selections. If you have problems in the rendering of certain character sets, try this option.

As from R 3.1.0 it also supports the `[inconsolata]` option, to render monospaced text in `inconsolata`, the font used by default for R help pages.

The use of fancy quotes (see [sQuote](#)) can cause problems when setting R output. Either set `options(useFancyQuotes = FALSE)` or arrange that LaTeX is aware of the encoding used (by a `\usepackage[utf8]{inputenc}` declaration: Windows users of Sweave from `Rgui.exe` will need to replace `utf8` by `cp1252` or similar) and ensure that typewriter fonts containing directional quotes are used.

Some LaTeX graphics drivers do not include `.png` or `.jpg` in the list of known extensions. To enable them, add something like `\DeclareGraphicsExtensions{.png,.pdf,.jpg}` to the preamble of your document or check the behavior of your graphics driver. When both pdf and png are TRUE both files will be produced by Sweave, and their order in the `\DeclareGraphicsExtensions` list determines which will be used by `pdflatex`.

## Supported Options

RweaveLatex supports the following options for code chunks (the values in parentheses show the default values). Character string values should be quoted when passed from [Sweave](#) through ... but not when use in the header of a code chunk.

**engine:** character string (`"R"`). Only chunks with engine equal to `"R"` or `"S"` are processed.

**echo:** logical (`TRUE`). Include R code in the output file?

**keep.source:** logical (`TRUE`). When echoing, if `keep.source == TRUE` the original source is copied to the file. Otherwise, deparsed source is echoed.

**eval:** logical (`TRUE`). If `FALSE`, the code chunk is not evaluated, and hence no text nor graphical output produced.

**results:** character string (`"verbatim"`). If `"verbatim"`, the output of R commands is included in the verbatim-like `Soutput` environment. If `"tex"`, the output is taken to be already proper LaTeX markup and included as is. If `"hide"` then all output is completely suppressed (but the code executed during the weave). Values can be abbreviated.

- print:** logical (FALSE). If TRUE, this forces auto-printing of all expressions.
- term:** logical (TRUE). If TRUE, visibility of values emulates an interactive R session: values of assignments are not printed, values of single objects are printed. If FALSE, output comes only from explicit `print` or similar statements.
- split:** logical (FALSE). If TRUE, text output is written to separate files for each code chunk.
- strip.white:** character string ("true"). If "true", blank lines at the beginning and end of output are removed. If "all", then all blank lines are removed from the output. If "false" then blank lines are retained.  
A 'blank line' is one that is empty or includes only whitespace (spaces and tabs).  
Note that blank lines in a code chunk will usually produce a prompt string rather than a blank line on output.
- prefix:** logical (TRUE). If TRUE generated filenames of figures and output all have the common prefix given by the `prefix.string` option: otherwise only unlabelled chunks use the prefix.
- prefix.string:** a character string, default is the name of the source file (without extension). Note that this is used as part of filenames, so needs to be portable.
- include:** logical (TRUE), indicating whether input statements for text output (if `split = TRUE`) and `'\includegraphics'` statements for figures should be auto-generated. Use `include = FALSE` if the output should appear in a different place than the code chunk (by placing the input line manually).
- fig:** logical (FALSE), indicating whether the code chunk produces graphical output. Note that only one figure per code chunk can be processed this way. The labels for figure chunks are used as part of the file names, so should preferably be alphanumeric.
- eps:** logical (FALSE), indicating whether EPS figures should be generated. Ignored if `fig = FALSE`.
- pdf:** logical (TRUE), indicating whether PDF figures should be generated. Ignored if `fig = FALSE`.
- pdf.version, pdf.encoding, pdf.compress:** passed to `pdf` to set the version, encoding and compression (or not). Defaults taken from `pdf.options()`.
- png:** logical (FALSE), indicating whether PNG figures should be generated. Ignored if `fig = FALSE`. Only available in R  $\geq$  2.13.0.
- jpeg:** logical (FALSE), indicating whether JPEG figures should be generated. Ignored if `fig = FALSE`. Only available in R  $\geq$  2.13.0.
- grdevice:** character (NULL): see section 'Custom Graphics Devices'. Ignored if `fig = FALSE`. Only available in R  $\geq$  2.13.0.
- width:** numeric (6), width of figures in inches. See 'Details'.
- height:** numeric (6), height of figures in inches. See 'Details'.
- resolution:** numeric (300), resolution in pixels per inch: used for PNG and JPEG graphics. Note that the default is a fairly high value, appropriate for high-quality plots. Something like 100 is a better choice for package vignettes.
- concordance:** logical (FALSE). Write a concordance file to link the input line numbers to the output line numbers. This is an experimental feature; see the source code for the output format, which is subject to change in future releases.
- figs.only:** logical (FALSE). By default each figure chunk is run once, then re-run for each selected type of graphics. That will open a default graphics device for the first figure chunk and use that device for the first evaluation of all subsequent chunks. If this option is true, the figure chunk is run only for each selected type of graphics, for which a new graphics device is opened and then closed.

In addition, users can specify further options, either in the header of an individual code section or in a ‘\SweaveOpts{ }’ line in the document. For unknown options, their type is set at first use.

### Custom Graphics Devices

If option `grdevice` is supplied for a code chunk with both `fig` and `eval` true, the following call is made

```
get(options$grdevice, envir = .GlobalEnv)(name=, width=,
                                           height=, options)
```

which should open a graphics device. The chunk’s code is then evaluated and `dev.off` is called. Normally a function of the name given will have been defined earlier in the Sweave document, e.g.

```
<<results=hide>>=
my.Swd <- function(name, width, height, ...)
  grDevices::png(filename = paste(name, "png", sep = "."),
                 width = width, height = height, res = 100,
                 units = "in", type = "quartz", bg = "transparent")
@
```

Currently only one custom device can be used for each chunk, but different devices can be used for different chunks.

A replacement for `dev.off` can be provided as a function with suffix `.off`, e.g. `my.Swd.off()`.

### Hook Functions

Before each code chunk is evaluated, zero or more hook functions can be executed. If `getOption("SweaveHooks")` is set, it is taken to be a named list of hook functions. For each *logical* option of a code chunk (`echo`, `print`, ...) a hook can be specified, which is executed if and only if the respective option is TRUE. Hooks must be named elements of the list returned by `getOption("SweaveHooks")` and be functions taking no arguments. E.g., if option "SweaveHooks" is defined as `list(fig = foo)`, and `foo` is a function, then it would be executed before the code in each figure chunk. This is especially useful to set defaults for the graphical parameters in a series of figure chunks.

Note that the user is free to define new Sweave logical options and associate arbitrary hooks with them. E.g., one could define a hook function for a new option called `clean` that removes all objects in the workspace. Then all code chunks specified with `clean = TRUE` would start operating on an empty workspace.

|             |                                                     |
|-------------|-----------------------------------------------------|
| savehistory | <i>Load or Save or Display the Commands History</i> |
|-------------|-----------------------------------------------------|

---

## Description

Load or save or display the commands history.

## Usage

```
loadhistory(file = ".Rhistory")
savehistory(file = ".Rhistory")

history(max.show = 25, reverse = FALSE, pattern, ...)

timestamp(stamp = date(),
           prefix = "##----- ", suffix = " -----##",
           quiet = FALSE)
```

## Arguments

|          |                                                                                                                                     |
|----------|-------------------------------------------------------------------------------------------------------------------------------------|
| file     | The name of the file in which to save the history, or from which to load it. The path is relative to the current working directory. |
| max.show | The maximum number of lines to show. Inf will give all of the currently available history.                                          |
| reverse  | logical. If true, the lines are shown in reverse order. Note: this is not useful when there are continuation lines.                 |
| pattern  | A character string to be matched against the lines of the history. When supplied, only <i>unique</i> matching lines are shown.      |
| ...      | Arguments to be passed to <a href="#">grep</a> when doing the matching.                                                             |
| stamp    | A value or vector of values to be written into the history.                                                                         |
| prefix   | A prefix to apply to each line.                                                                                                     |
| suffix   | A suffix to apply to each line.                                                                                                     |
| quiet    | If TRUE, suppress printing timestamp to the console.                                                                                |

## Details

There are several history mechanisms available for the different R consoles, which work in similar but not identical ways. There are separate versions of this help file for Unix and Windows.

The functions described here work on Unix-alikes under the `readline` command-line interface but may not otherwise (for example, in batch use or in an embedded application). Note that R can be built without `readline`.

R.app, the console on OS X, has a separate and largely incompatible history mechanism, which by default uses a file `‘.Rapp.history’` and saves up to 250 entries. These functions are not currently implemented there.

The readline history mechanism is controlled by two environment variables: `R_HISTSIZE` controls the number of lines that are saved (default 512), and `R_HISTFILE` (default `‘.Rhistory’`) sets the filename used for the loading/saving of history if requested at the beginning/end of a session (but not the default for `loadhistory/savehistory`). There is no limit on the number of lines of history retained during a session, so setting `R_HISTSIZE` to a large value has no penalty unless a large file is actually generated.

These environment variables are read at the time of saving, so can be altered within a session by the use of [Sys.setenv](#).

Note that readline history library saves files with permission `0600`, that is with read/write permission for the user and not even read permission for any other account.

The `timestamp` function writes a timestamp (or other message) into the history and echos it to the console. On platforms that do not support a history mechanism only the console message is printed.

### Note

If you want to save the history at the end of (almost) every interactive session (even those in which you do not save the workspace), you can put a call to `savehistory()` in [.Last](#). See the examples.

### Examples

```
## Not run:
## Save the history in the home directory: note that it is not
## (by default) read from there but from the current directory
.Last <- function()
  if(interactive()) try(savehistory("~/Rhistory"))

## End(Not run)
```

---

select.list

*Select Items from a List*

---

### Description

Select item(s) from a character vector.

### Usage

```
select.list(choices, preselect = NULL, multiple = FALSE,
            title = NULL, graphics = getOption("menu.graphics"))
```

### Arguments

|                        |                                                                                                                                     |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>choices</code>   | a character vector of items.                                                                                                        |
| <code>preselect</code> | a character vector, or <code>NULL</code> . If non-null and if the string(s) appear in the list, the item(s) are selected initially. |
| <code>multiple</code>  | logical: can more than one item be selected?                                                                                        |
| <code>title</code>     | optional character string for window title, or <code>NULL</code> for no title.                                                      |
| <code>graphics</code>  | logical: should a graphical widget be used?                                                                                         |

### Details

The normal default is `graphics = TRUE`. Under the OS X GUI this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse. On other Unix-like platforms it will use a Tcl/Tk listbox widget if possible.

If `graphics` is `FALSE` or no graphical widget is available it displays a text list from which the user can choose by number(s). The `multiple = FALSE` case uses [menu](#). Preselection is only supported for `multiple = TRUE`, where it is indicated by a "+" preceding the item.

It is an error to use `select.list` in a non-interactive session.

### Value

A character vector of selected items. If `multiple` is false and no item was selected (or Cancel was used), "" is returned. If `multiple` is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

### See Also

[menu](#), [tk\\_select.list](#) for a graphical version using Tcl/Tk.

### Examples

```
## Not run:
select.list(sort(.packages(all.available = TRUE)))

## End(Not run)
```

---

sessionInfo

*Collect Information About the Current R Session*

---

### Description

Print version information about R, the OS and attached or loaded packages.

### Usage

```
sessionInfo(package = NULL)
## S3 method for class 'sessionInfo'
print(x, locale = TRUE, ...)
## S3 method for class 'sessionInfo'
toLatex(object, locale = TRUE, ...)
```

**Arguments**

|         |                                                                                                    |
|---------|----------------------------------------------------------------------------------------------------|
| package | a character vector naming installed packages, or NULL (the default) meaning all attached packages. |
| x       | an object of class "sessionInfo".                                                                  |
| object  | an object of class "sessionInfo".                                                                  |
| locale  | show locale information?                                                                           |
| ...     | currently not used.                                                                                |

**Value**

An object of class "sessionInfo", which has a print method. This is a list with components

|            |                                                                                                                                                               |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R.version  | a list, the result of calling <a href="#">R.Version()</a> .                                                                                                   |
| platform   | a character string describing the platform. Where sub-architectures are in use this is of the form 'platform/sub-arch (nn-bit)'.                              |
| running    | a character string describing the OS and version which it is running under (as distinct from compiled under).                                                 |
| locale     | a character string, the result of calling <a href="#">Sys.getlocale()</a> .                                                                                   |
| basePkgs   | a character vector of base packages which are attached.                                                                                                       |
| otherPkgs  | (not always present): a character vector of other attached packages.                                                                                          |
| loadedOnly | (not always present): a named list of the results of calling <a href="#">packageDescription</a> on packages whose namespaces are loaded but are not attached. |

**Note**

The information on 'loaded' packages and namespaces is the *current* version installed at the location the package was loaded from: it can be wrong if another process has been changing packages during the session.

How OSes identify themselves and their versions can be arcane: where possible running uses a human-readable form.

**See Also**

**Examples**

```
sessionInfo()
toLatex(sessionInfo(), locale = FALSE)
```

---

|                 |                                    |
|-----------------|------------------------------------|
| setRepositories | <i>Select Package Repositories</i> |
|-----------------|------------------------------------|

---

## Description

Interact with the user to choose the package repositories to be used.

## Usage

```
setRepositories(graphics = getOption("menu.graphics"),
               ind = NULL, addURLs = character())
```

## Arguments

|          |                                                                                                                                                                                                              |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| graphics | Logical. If true, use a graphical list: on Windows or OS X GUI use a list box, and on a Unix-alike if <b>tcltk</b> and an X server are available, use Tk widget. Otherwise use a text <a href="#">menu</a> . |
| ind      | NULL or a vector of integer indices, which have the same effect as if they were entered at the prompt for graphics = FALSE.                                                                                  |
| addURLs  | A character vector of additional URLs: it is often helpful to use a named vector.                                                                                                                            |

## Details

The default list of known repositories is stored in the file '[R\\_HOME](#)/etc/repositories'. That file can be edited for a site, or a user can have a personal copy in the file pointed to by the environment variable R\_REPOSITORIES, or if this is unset or does not exist, in '[HOME](#)/.R/repositories', which will take precedence.

A Bioconductor mirror can be selected by setting `options("BioC_mirror")`, e.g. via [chooseBioCmirror](#) — the default value is "`http://bioconductor.org`".

The items that are preselected are those that are currently in `options("repos")` plus those marked as default in the list of known repositories.

The list of repositories offered depends on the setting of option "pkgType" as some repositories only offer a subset of types (e.g., only source packages or not OS X binary packages). Further, for binary packages some repositories (notably R-Forge) only offer packages for the current or recent versions of R. (Type "both" is equivalent to "source".)

Repository 'CRAN' is treated specially: the value is taken from the current setting of `getOption("repos")` if this has an element "CRAN": this ensures mirror selection is sticky.

This function requires the R session to be interactive unless `ind` is supplied.

Some of the entries have https versions which use '`https://`' for access, so if selected need an R build which supports this. (Choosing the https version provides some guarantees on the identity of the site.)

**Value**

This function is invoked mainly for its side effect of updating `options("repos")`. It returns (invisibly) the previous repos options setting (as a [list](#) with component `repos`) or `NULL` if no changes were applied.

**Note**

This does **not** set the list of repositories at startup: to do so set `options(repos =)` in a start up file (see help topic [Startup](#)).

**See Also**

[chooseCRANmirror](#), [chooseBioCmirror](#), [install.packages](#).

**Examples**

```
## Not run:
setRepositories(addURLs =
  c(CRANxtras = "http://www.stats.ox.ac.uk/pub/RWin"))

## End(Not run)
```

|-------|----------------------------------------------------|
| SHLIB | <i>Build Shared Object/DLL for Dynamic Loading</i> |
|-------|----------------------------------------------------|

---

**Description**

Compile the given source files and then link all specified object files into a shared object aka DLL which can be loaded into R using `dyn.load` or `library.dynam`.

**Usage**

R CMD SHLIB [options] [-o dllname] files

**Arguments**

|         |                                                                                                                                                                                                                                                         |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| files   | a list specifying the object files to be included in the shared object/DLL. You can also include the name of source files (for which the object files are automagically made from their sources) and library linking commands.                          |
| dllname | the full name of the shared object/DLL to be built, including the extension (typically <code>.so</code> on Unix systems, and <code>.dll</code> on Windows). If not given, the base-name of the object/DLL is taken from the basename of the first file. |
| options | Further options to control the processing. Use <code>R CMD SHLIB --help</code> for a current list.                                                                                                                                                      |

## Details

R CMD SHLIB is the mechanism used by [INSTALL](#) to compile source code in packages. It will generate suitable compilation commands for C, C++, Objective C(++) and Fortran sources: Fortran 90/95 sources can also be used but it may not be possible to mix these with other languages (on most platforms it is possible to mix with C, but mixing with C++ rarely works).

Please consult section ‘Creating shared objects’ in the manual ‘Writing R Extensions’ for how to customize it (for example to add cpp flags and to add libraries to the link step) and for details of some of its quirks.

Items in files with extensions ‘.c’, ‘.cpp’, ‘.cc’, ‘.C’, ‘.f’, ‘.f90’, ‘.f95’, ‘.m’ (ObjC), ‘.M’ and ‘.mm’ (ObjC++) are regarded as source files, and those with extension ‘.o’ as object files. All other items are passed to the linker.

Objective C(++) support is optional when R was configured: their main usage is on OS X.

Note that the appropriate run-time libraries will be used when linking if C++, Fortran or Objective C(++) sources are supplied, but not for compiled object files from these languages.

Option ‘-n’ (also known as ‘--dry-run’) will show the commands that would be run without actually executing them.

## Note

Some binary distributions of R have SHLIB in a separate bundle, e.g., an R-devel RPM.

## See Also

[COMPILE](#), [dyn.load](#), [library.dynam](#).

The ‘R Installation and Administration’ and ‘Writing R Extensions’ manuals, including the section on “Customizing compilation” in the former.

## Examples

```
## Not run:
# To link against a library not on the system library paths:
R CMD SHLIB -o mylib.so a.f b.f -L/opt/acml3.5.0/gnu64/lib -lacml

## End(Not run)
```

## Description

These functions extract information from source references.

## Usage

```
getSrcFilename(x, full.names = FALSE, unique = TRUE)
getSrcDirectory(x, unique = TRUE)
getSrcref(x)
getSrcLocation(x, which = c("line", "column", "byte", "parse"),
               first = TRUE)
```

## Arguments

|                         |                                                                  |
|-------------------------|------------------------------------------------------------------|
| <code>x</code>          | An object (typically a function) containing source references.   |
| <code>full.names</code> | Whether to include the full path in the filename result.         |
| <code>unique</code>     | Whether to list only unique filenames/directories.               |
| <code>which</code>      | Which part of a source reference to extract. Can be abbreviated. |
| <code>first</code>      | Whether to show the first (or last) location of the object.      |

## Details

Each statement of a function will have its own source reference if the "keep.source" option is TRUE. These functions retrieve all of them.

The components are as follows:

**line** The line number where the object starts or ends.

**column** The column number where the object starts or ends.

**byte** As for "column", but counting bytes, which may differ in case of multibyte characters.

**parse** As for "line", but this ignores #line directives.

## Value

`getSrcFilename` and `getSrcDirectory` return character vectors holding the filename/directory.

`getSrcref` returns a list of "srcref" objects or NULL if there are none.

`getSrcLocation` returns an integer vector of the requested type of locations.

## See Also

[srcref](#), [getParseData](#)

## Examples

```
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

# Show the temporary file directory
# where the example was saved

getSrcDirectory(fn)
getSrcLocation(fn, "line")
```

---

stack*Stack or Unstack Vectors from a Data Frame or List*

---

## Description

Stacking vectors concatenates multiple vectors into a single vector along with a factor indicating where each observation originated. Unstacking reverses this operation.

## Usage

```
stack(x, ...)
## Default S3 method:
stack(x, ...)
## S3 method for class 'data.frame'
stack(x, select, ...)

unstack(x, ...)
## Default S3 method:
unstack(x, form, ...)
## S3 method for class 'data.frame'
unstack(x, form, ...)
```

## Arguments

|        |                                                                                                                                                                                                                                |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | a list or data frame to be stacked or unstacked.                                                                                                                                                                               |
| select | an expression, indicating which variable(s) to select from a data frame.                                                                                                                                                       |
| form   | a two-sided formula whose left side evaluates to the vector to be unstacked and whose right side evaluates to the indicator of the groups to create. Defaults to <code>formula(x)</code> in the data frame method for unstack. |
| ...    | further arguments passed to or from other methods.                                                                                                                                                                             |

## Details

The `stack` function is used to transform data available as separate columns in a data frame or list into a single column that can be used in an analysis of variance model or other linear model. The `unstack` function reverses this operation.

Note that `stack` applies to *vectors* (as determined by `is.vector`): non-vector columns (e.g., factors) will be ignored (with a warning as from R 2.15.0). Where vectors of different types are selected they are concatenated by `unlist` whose help page explains how the type of the result is chosen.

These functions are generic: the supplied methods handle data frames and objects coercible to lists by `as.list`.

**Value**

unstack produces a list of columns according to the formula form. If all the columns have the same length, the resulting list is coerced to a data frame.

stack produces a data frame with two columns:

|        |                                                                        |
|--------|------------------------------------------------------------------------|
| values | the result of concatenating the selected vectors in x.                 |
| ind    | a factor indicating from which vector in x the observation originated. |

[lm](#), [reshape](#)

**Examples**

```
require(stats)
formula(PlantGrowth)      # check the default formula
pg <- unstack(PlantGrowth) # unstack according to this formula
pg
stack(pg)                  # now put it back together
stack(pg, select = -ctrl)  # omitting one vector
```

---

str

*Compactly Display the Structure of an Arbitrary R Object*

---

**Description**

Compactly display the internal **structure** of an R object, a diagnostic function and an alternative to [summary](#) (and to some extent, [dput](#)). Ideally, only one line for each ‘basic’ structure is displayed. It is especially well suited to compactly display the (abbreviated) contents of (possibly nested) lists. The idea is to give reasonable output for **any** R object. It calls [args](#) for (non-primitive) function objects.

strOptions() is a convenience function for setting [options](#)(str = .), see the examples.

**Usage**

```
str(object, ...)
```

```
## S3 method for class 'data.frame'
str(object, ...)
```

```
## Default S3 method:
str(object, max.level = NA,
      vec.len = str0$vec.len, digits.d = str0$digits.d,
```

```

nchar.max = 128, give.attr = TRUE,
give.head = TRUE, give.length = give.head,
width = getOption("width"), nest.lev = 0,
indent.str = paste(rep.int(" ", max(0, nest.lev + 1)),
                    collapse = "..."),
comp.str = "$ ", no.list = FALSE, envir = baseenv(),
strict.width = str0$strict.width,
formatNum = str0$formatNum, list.len = 99, ...)

strOptions(strict.width = "no", digits.d = 3, vec.len = 4,
           formatNum = function(x, ...)
             format(x, trim = TRUE, drop0trailing = TRUE, ...))

```

## Arguments

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>       | any R object about which you want to have some information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>max.level</code>    | maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default NA: Display all nesting levels.                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>vec.len</code>      | numeric ( $\geq 0$ ) indicating how many ‘first few’ elements are displayed of each vector. The number is multiplied by different factors (from .5 to 3) depending on the kind of vector. Defaults to the <code>vec.len</code> component of option “str” (see <a href="#">options</a> ) which defaults to 4.                                                                                                                                                                                                                            |
| <code>digits.d</code>     | number of digits for numerical components (as for <a href="#">print</a> ). Defaults to the <code>digits.d</code> component of option “str” which defaults to 3.                                                                                                                                                                                                                                                                                                                                                                         |
| <code>nchar.max</code>    | maximal number of characters to show for <a href="#">character</a> strings. Longer strings are truncated, see longch example below.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>give.attr</code>    | logical; if TRUE (default), show attributes as sub structures.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>give.length</code>  | logical; if TRUE (default), indicate length (as <code>[1:...] </code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>give.head</code>    | logical; if TRUE (default), give (possibly abbreviated) mode/class and length (as <code>&lt;type&gt;[1:...] </code> ).                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>width</code>        | the page width to be used. The default is the currently active <a href="#">options</a> (“width”); note that this has only a weak effect, unless <code>strict.width</code> is not “no”.                                                                                                                                                                                                                                                                                                                                                  |
| <code>nest.lev</code>     | current nesting level in the recursive calls to <code>str</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>indent.str</code>   | the indentation string to use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>comp.str</code>     | string to be used for separating list components.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>no.list</code>      | logical; if true, no ‘list of ...’ nor the class are printed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>envir</code>        | the environment to be used for <i>promise</i> (see <a href="#">delayedAssign</a> ) objects only.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>strict.width</code> | string indicating if the width argument’s specification should be followed strictly, one of the values <code>c("no", "cut", "wrap")</code> , which can be abbreviated. Defaults to the <code>strict.width</code> component of option “str” (see <a href="#">options</a> ) which defaults to “no” for back compatibility reasons; “wrap” uses <a href="#">strwrap</a> (*, width = width) whereas “cut” cuts directly to width. Note that a small <code>vec.length</code> may be better than setting <code>strict.width = "wrap"</code> . |

|           |                                                                                                                                                                                                                                                                                    |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formatNum | a function such as <a href="#">format</a> for formatting numeric vectors. It defaults to the formatNum component of option "str", see "Usage" of strOptions() above, which is almost back compatible to R <= 2.7.x, however, using <a href="#">formatC</a> may be slightly better. |
| list.len  | numeric; maximum number of list elements to display within a level.                                                                                                                                                                                                                |
| ...       | potential further arguments (required for Method/Generic reasons).                                                                                                                                                                                                                 |

### Value

str does not return anything, for efficiency reasons. The obvious side effect is output to the terminal.

### Author(s)

Martin Maechler <maechler@stat.math.ethz.ch> since 1990.

summaryRprof

*Summarise Output of R Sampling Profiler***Description**

Summarise the output of the [Rprof](#) function to show the amount of time used by different R functions.

**Usage**

```
summaryRprof(filename = "Rprof.out", chunksize = 5000,
             memory = c("none", "both", "tseries", "stats"),
             lines = c("hide", "show", "both"),
             index = 2, diff = TRUE, exclude = NULL,
             basenames = 1)
```

**Arguments**

|           |                                                                                     |
|-----------|-------------------------------------------------------------------------------------|
| filename  | Name of a file produced by Rprof().                                                 |
| chunksize | Number of lines to read at a time.                                                  |
| memory    | Summaries for memory information. See ‘Memory profiling’ below. Can be abbreviated. |
| lines     | Summaries for line information. See ‘Line profiling’ below. Can be abbreviated.     |
| index     | How to summarize the stack trace for memory information. See ‘Details’ below.       |

|           |                                                                             |
|-----------|-----------------------------------------------------------------------------|
| diff      | If TRUE memory summaries use change in memory rather than current memory.   |
| exclude   | Functions to exclude when summarizing the stack trace for memory summaries. |
| basenames | Number of components of the path to filenames to display.                   |

## Details

This function provides the analysis code for [Rprof](#) files used by R CMD Rprof.

As the profiling output file could be larger than available memory, it is read in blocks of chunksize lines. Increasing chunksize will make the function run faster if sufficient memory is available.

## Value

If memory = "none" and lines = "hide", a list with components

by.self            A data frame of timings sorted by 'self' time.

by.total          A data frame of timings sorted by 'total' time.

sample.interval  
                  The sampling interval.

sampling.time    Total time of profiling run.

The first two components have columns 'self.time', 'self.pct', 'total.time' and 'total.pct', the times in seconds and percentages of the total time spent executing code in that function and code in that function or called from that function, respectively.

If lines = "show", an additional component is added to the list:

by.line           A data frame of timings sorted by source location.

If memory = "both" the same list but with memory consumption in Mb in addition to the timings.

If memory = "tseries" a data frame giving memory statistics over time.

If memory = "stats" a [by](#) object giving memory statistics by function.

Prior to R 2.15.3 an error was thrown if no events were recorded: now zero-row data frames are returned.

## Memory profiling

Options other than memory = "none" apply only to files produced by [Rprof](#)(memory.profiling = TRUE).

When called with memory.profiling = TRUE, the profiler writes information on three aspects of memory use: vector memory in small blocks on the R heap, vector memory in large blocks (from malloc), memory in nodes on the R heap. It also records the number of calls to the internal function duplicate in the time interval. duplicate is called by C code when arguments need to be copied. Note that the profiler does not track which function actually allocated the memory.

With memory = "both" the change in total memory (truncated at zero) is reported in addition to timing data.

With memory = "tseries" or memory = "stats" the index argument specifies how to summarize the stack trace. A positive number specifies that many calls from the bottom of the stack; a negative number specifies the number of calls from the top of the stack. With memory = "tseries"

the index is used to construct labels and may be a vector to give multiple sets of labels. With `memory = "stats"` the index must be a single number and specifies how to aggregate the data to the maximum and average of the memory statistics. With both `memory = "tseries"` and `memory = "stats"` the argument `diff = TRUE` asks for summaries of the increase in memory use over the sampling interval and `diff = FALSE` asks for the memory use at the end of the interval.

### Line profiling

If the code being run has source reference information retained (via `keep.source = TRUE` in `source` or `KeepSource = TRUE` in a package ‘DESCRIPTION’ file or some other way), then information about the origin of lines is recorded during profiling. By default this is not displayed, but the `lines` parameter can enable the display.

If `lines = "show"`, line locations will be used in preference to the usual function name information, and the results will be displayed ordered by location in addition to the other orderings.

If `lines = "both"`, line locations will be mixed with function names in a combined display.

The chapter on “Tidying and profiling R code” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

[Rprof](#)

[tracemem](#) traces copying of an object via the C function `duplicate`.

[Rprofmem](#) is a non-sampling memory-use profiler.

<http://developer.r-project.org/memory-profiling.html>

### Examples

```
## Not run:
## Rprof() is not available on all platforms
Rprof(tmp <- tempfile())
example(glm)
Rprof()
summaryRprof(tmp)
unlink(tmp)

## End(Not run)
```

### Description

Sweave provides a flexible framework for mixing text and R/S code for automatic report generation. The basic idea is to replace the code with its output, such that the final document only contains the text and the output of the statistical analysis: however, the source code can also be included.

**Usage**

```
Sweave(file, driver = RweaveLatex(),
       syntax = getOption("SweaveSyntax"), encoding = "", ...)

Stangle(file, driver = Rtangle(),
       syntax = getOption("SweaveSyntax"), encoding = "", ...)
```

**Arguments**

|                       |                                                                                                                                                                                                                      |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>     | Path to Sweave source file. Note that this can be supplied without the extension, but the function will only proceed if there is exactly one Sweave file in the directory whose basename matches <code>file</code> . |
| <code>driver</code>   | The actual workhorse, see ‘Details’.                                                                                                                                                                                 |
| <code>syntax</code>   | NULL or an object of class <code>SweaveSyntax</code> or a character string with its name. See the section ‘Syntax Definition’.                                                                                       |
| <code>encoding</code> | The default encoding to assume for <code>file</code> .                                                                                                                                                               |
| <code>...</code>      | Further arguments passed to the driver’s setup function: see section ‘Drivers’, <a href="#">RweaveLatex</a> and <a href="#">Rtangle</a> .                                                                            |

**Details**

Automatic generation of reports by mixing word processing markup (like `latex`) and S code. The S code gets replaced by its output (text or graphs) in the final markup file. This allows a report to be re-generated if the input data change and documents the code to reproduce the analysis in the same file that also produces the report.

Sweave combines the documentation and code chunks together (or their output) into a single document. Stangle extracts only the code from the Sweave file creating an S source file that can be run using [source](#). (Code inside `\Sexpr{}` statements is ignored by Stangle.)

Stangle is just a wrapper to Sweave specifying a different default driver. Alternative drivers can be used: the CRAN package **cacheSweave** and the Bioconductor package **weaver** both provide drivers based on the default driver [RweaveLatex](#) which incorporate ideas of *caching* the results of computations on code chunks.

Environment variable `SWEAVE_OPTIONS` can be used to override the initial options set by the driver: it should be a comma-separated set of `key=value` items, as would be used in a ‘`\SweaveOpts`’ statement in a document.

Non-ASCII source files must contain a line of the form

```
\usepackage[foo]{inputenc}
```

(where ‘foo’ is typically ‘`latin1`’, ‘`latin2`’, ‘`utf8`’ or ‘`cp1252`’ or ‘`cp1250`’) or they will give an error. Re-encoding can be turned off completely with argument `encoding = "bytes"`.

**Syntax Definition**

Sweave allows a flexible syntax framework for marking documentation and text chunks. The default is a noweb-style syntax, as alternative a `latex`-style syntax can be used. (See the user manual for further details.)

If `syntax = NULL` (the default) then the available syntax objects are consulted in turn, and selected if their extension component matches (as a regexp) the file name. Objects `SweaveSyntaxNoweb` (with `extension = "[rsRS]nw$"`) and `SweaveSyntaxLatex` (with `extension = "[rsRS]tex$"`) are supplied, but users or packages can supply others with names matching the pattern `SweaveSyntax.*`.

Packages **cacheSweave**, **weaver** (Bioconductor) and **SweaveListingUtils**.

Further Sweave drivers are in, for example, packages **R2HTML**, **ascii**, **odfWeave** and **pgfSweave**.

Non-Sweave vignettes may be built with tools: [:buildVignette](#).

### Examples

```
testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

## enforce par(ask = FALSE)
options(device.ask.default = FALSE)

## create a LaTeX file
Sweave(testfile)

## This can be compiled to PDF by
## tools::texi2pdf("Sweave-test-1.tex")
## or outside R by
## R CMD texi2pdf Sweave-test-1.tex
## which sets the appropriate TEXINPUTS path.

## create an R source file from the code chunks
Stangle(testfile)
## which can be sourced, e.g.
source("Sweave-test-1.R")
```

SweaveSyntConv

*Convert Sweave Syntax*

---

**Description**

This function converts the syntax of files in [Sweave](#) format to another Sweave syntax definition.

**Usage**

```
SweaveSyntConv(file, syntax, output = NULL)
```

**Arguments**

|        |                                                                                                                                                                                                                                                   |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file   | Name of Sweave source file.                                                                                                                                                                                                                       |
| syntax | An object of class SweaveSyntax or a character string with its name giving the target syntax to which the file is converted.                                                                                                                      |
| output | Name of output file, default is to remove the extension from the input file and to add the default extension of the target syntax. Any directory names in file are also removed such that the output is created in the current working directory. |

**Author(s)**

Friedrich Leisch

**See Also**

[‘Sweave User Manual’](#), a vignette in the **utils** package.

[RweaveLatex](#), [Rtangle](#)

**Examples**

```
testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

## convert the file to latex syntax
SweaveSyntConv(testfile, SweaveSyntaxLatex)

## and run it through Sweave
Sweave("Sweave-test-1.Stex")
```

## tar

*Create a Tar Archive***Description**

Create a tar archive.

**Usage**

```
tar(tarfile, files = NULL,
    compression = c("none", "gzip", "bzip2", "xz"),
    compression_level = 6, tar = Sys.getenv("tar"),
    extra_flags = "")
```

**Arguments**

|                   |                                                                                                                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tarfile           | The pathname of the tar file: tilde expansion (see <a href="#">path.expand</a> ) will be performed. Alternatively, a <a href="#">connection</a> that can be used for binary writes.                                                   |
| files             | A character vector of filepaths to be archived: the default is to archive all files under the current directory.                                                                                                                      |
| compression       | character string giving the type of compression to be used (default none). Can be abbreviated.                                                                                                                                        |
| compression_level | integer: the level of compression. Only used for the internal method.                                                                                                                                                                 |
| tar               | character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted (e.g., by <a href="#">shQuote</a> ) – but argument tar can also contain flags separated from the command by spaces. |
| extra_flags       | any extra flags for an external tar.                                                                                                                                                                                                  |

**Details**

This is either a wrapper for a tar command or uses an internal implementation in R. The latter is used if tarfile is a connection or if the argument tar is "internal" or "" (the 'factory-fresh' default). Note that whereas Unix-alike versions of R set the environment variable TAR, its value is not the default for this function.

Argument extra\_flags is passed to an external tar and so is platform-dependent. Possibly useful values include '-h' (follow symbolic links, also '-L' on some platforms), '--acls', '--exclude-backups', '--exclude-vcs' (and similar) and on Windows '--force-local' (so drives can be included in filepaths: however, this is the default for the Rtools tar). For GNU tar, '--format=ustar' forces a more portable format. (The default is set at compilation and will be shown at the end of the output from tar --help: for version 1.28 'out-of-the-box' it is '--format=gnu', but the manual says the intention is to change to '--format=pax' which GNU incorrectly calls 'POSIX' – it was never part of the POSIX standard for tar and should not be used.) For libarchive's bsdtar, '--format=ustar' is more portable than the default.

## Value

The return code from `system` or 0 for the internal version, invisibly.

## Portability

The ‘tar’ format no longer has an agreed standard! ‘Unix Standard Tar’ was part of POSIX 1003.1:1998 but has been removed in favour of pax, and in any case many common implementations diverged from the former standard. Many R platforms use a version of GNU tar (including Rtools on Windows), but the behaviour seems to be changed with each version. OS X  $\geq$  10.6 and FreeBSD use bsdtar from the ‘libarchive’ project, and commercial Unixes will have their own versions.

Known problems arise from

- The handling of file paths of more than 100 bytes. These were unsupported in early versions of tar, and supported in one way by POSIX tar and in another by GNU tar and yet another by the POSIX pax command which recent tar programs often support. The internal implementation warns on paths of more than 100 bytes, uses the ‘ustar’ way from the 1998 POSIX standard which supports up to 256 bytes (depending on the path: in particular the final component is limited to 100 bytes) if possible, otherwise the GNU way (which is widely supported, including by `untar`).

Most formats do not record the encoding of file paths.

- (File) links. tar was developed on an OS that used hard links, and physical files that were referred to more than once in the list of files to be included were included only once, the remaining instances being added as links. Later a means to include symbolic links was added. The internal implementation supports symbolic links (on OSes that support them), only. Of course, the question arises as to how links should be unpacked on OSes that do not support them: for regular files file copies can be used.

Names of links in the ‘ustar’ format are restricted to 100 bytes. There is an GNU extension for arbitrarily long link names, but bsdtar ignores it. The internal method uses the GNU extension, with a warning.

- Header fields, in particular the padding to be used when fields are not full or not used. POSIX did define the correct behaviour but commonly used implementations did (and still do) not comply.
- File sizes. The ‘ustar’ format is restricted to 8GB per (uncompressed) file.

For portability, avoid file paths of more than 100 bytes and all links (especially hard links and symbolic links to directories).

The internal implementation writes only the blocks of 512 bytes required (including trailing blocks of nuls), unlike GNU tar which by default pads with ‘nul’ to a multiple of 20 blocks (10KB). Implementations which pad differ on whether the block padding should occur before or after compression (or both): padding was designed for improved performance on physical tape drives.

[untar](#).

---

toLatex

*Converting R Objects to BibTeX or LaTeX*

---

## Description

These methods convert R objects to character vectors with BibTeX or LaTeX markup.

## Usage

```
toBibtex(object, ...)  
toLatex(object, ...)  
## S3 method for class 'Bibtex'  
print(x, prefix = "", ...)  
## S3 method for class 'Latex'  
print(x, prefix = "", ...)
```

## Arguments

|        |                                                                                                                      |
|--------|----------------------------------------------------------------------------------------------------------------------|
| object | object of a class for which a toBibtex or toLatex method exists.                                                     |
| x      | object of class "Bibtex" or "Latex".                                                                                 |
| prefix | a character string which is printed at the beginning of each line, mostly used to insert whitespace for indentation. |
| ...    | in the print methods, passed to <a href="#">writeLines</a> .                                                         |

## Details

Objects of class "Bibtex" or "Latex" are simply character vectors where each element holds one line of the corresponding BibTeX or LaTeX file.

|----------------|--------------------------|
| txtProgressBar | <i>Text Progress Bar</i> |
|----------------|--------------------------|

---

## Description

Text progress bar in the R console.

## Usage

```
txtProgressBar(min = 0, max = 1, initial = 0, char = "=",
              width = NA, title, label, style = 1, file = "")

getTxtProgressBar(pb)
setTxtProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'txtProgressBar'
close(con, ...)
```

## Arguments

|                |                                                                                                                                                                           |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| min, max       | (finite) numeric values for the extremes of the progress bar. Must have min < max.                                                                                        |
| initial, value | initial or new value for the progress bar. See ‘Details’ for what happens with invalid values.                                                                            |
| char           | the character (or character string) to form the progress bar.                                                                                                             |
| width          | the width of the progress bar, as a multiple of the width of char. If NA, the default, the number of characters is that which fits into <code>getOption("width")</code> . |
| style          | the ‘style’ of the bar – see ‘Details’.                                                                                                                                   |
| file           | an open connection object or "" which indicates the console: <code>stderr()</code> might be useful here.                                                                  |
| pb, con        | an object of class "txtProgressBar".                                                                                                                                      |
| title, label   | ignored, for compatibility with other progress bars.                                                                                                                      |
| ...            | for consistency with the generic.                                                                                                                                         |

## Details

txtProgressBar will display a progress bar on the R console (or a connection) via a text representation.

setTxtProgressBar will update the value. Missing (NA) and out-of-range values of value will be (silently) ignored. (Such values of initial cause the progress bar not to be displayed until a valid value is set.)

The progress bar should be closed when finished with: this outputs the final newline character.

style = 1 and style = 2 just shows a line of char. They differ in that style = 2 redraws the line each time, which is useful if other code might be writing to the R console. style = 3 marks the end of the range by | and gives a percentage to the right of the bar.

**Value**

For txtProgressBar an object of class "txtProgressBar".

For getTxtProgressBar and setTxtProgressBar, a length-one numeric vector giving the previous value (invisibly for setTxtProgressBar).

**Note**

Using style 2 or 3 or reducing the value with style = 1 uses '\r' to return to the left margin – the interpretation of carriage return is up to the terminal or console in which R is running, and this is liable to produce ugly output on a connection other than a terminal, including when stdout() is redirected to a file.

**See Also**

[tkProgressBar](#).

Windows versions of R also have winProgressBar.

**Examples**

```
# slow
testit <- function(x = sort(runif(20)), ...)
{
  pb <- txtProgressBar(...)
  for(i in c(0, x, 1)) {Sys.sleep(0.5); setTxtProgressBar(pb, i)}
  Sys.sleep(1)
  close(pb)
}
testit()
testit(runif(10))
testit(style = 3)
```

---

type.convert

Type Conversion on Character Variables

---

**Description**

Convert a character vector to logical, integer, numeric, complex or factor as appropriate.

**Usage**

```
type.convert(x, na.strings = "NA", as.is = FALSE, dec = ".",
             numerals = c("allow.loss", "warn.loss", "no.loss"))
```

### Arguments

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x          | a character vector.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| na.strings | a vector of strings which are to be interpreted as <a href="#">NA</a> values. Blank fields are also considered to be missing values in logical, integer, numeric or complex vectors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| as.is      | logical. See ‘Details’.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| dec        | the character to be assumed for decimal points.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| numerals   | <p>string indicating how to convert numbers whose conversion to double precision would lose accuracy, typically when x has more digits than can be stored in a <a href="#">double</a>. Can be abbreviated. Possible values are</p> <p>numerals = "allow.loss", <b>default:</b> the conversion happens with some accuracy loss. This has been the only behavior of R versions 3.0.3 and earlier.</p> <p>numerals = "warn.loss": a <a href="#">warning</a> about accuracy loss is signalled and the conversion happens as with numerals = "allow.loss".</p> <p>numerals = "no.loss": x is <i>not</i> converted to a number, but to a <a href="#">factor</a> or left as character, depending on as.is. This has been the only behavior of R version 3.1.0.</p> |

### Details

This is principally a helper function for [read.table](#). Given a character vector, it attempts to convert it to logical, integer, numeric or complex, and failing that converts it to factor unless as.is = TRUE. The first type that can accept all the non-missing values is chosen.

Vectors which are entirely missing values are converted to logical, since NA is primarily logical.

Vectors containing just F, T, FALSE, TRUE and values from na.strings are converted to logical. Vectors containing optional whitespace followed by decimal constants representable as R integers or values from na.strings are converted to integer. Other vectors containing optional whitespace followed by other decimal or hexadecimal constants (see [NumericConstants](#)), or NaN, Inf or infinity (ignoring case) or values from na.strings are converted to numeric. Where converting inputs to numeric or complex would result in loss of accuracy they can optionally be returned as strings (for as.is = TRUE) or factors.

Since this is a helper function, the caller should always pass an appropriate value of as.is.

### Value

An atomic vector or (for as.is = FALSE) a factor.

| untar | <i>Extract or List Tar Archives</i> |
|-------|-------------------------------------|

---

## Description

Extract files from or list the contents of a tar archive.

## Usage

```
untar(tarfile, files = NULL, list = FALSE, exdir = ".",
      compressed = NA, extras = NULL, verbose = FALSE,
      restore_times = TRUE, tar = Sys.getenv("TAR"))
```

## Arguments

|               |                                                                                                                                                                                                                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tarfile       | The pathname of the tar file: tilde expansion (see <a href="#">path.expand</a> ) will be performed. Alternatively, a <a href="#">connection</a> that can be used for binary reads.                                                                                                                                                                        |
| files         | A character vector of recorded filepaths to be extracted: the default is to extract all files.                                                                                                                                                                                                                                                            |
| list          | If TRUE, list the files (the equivalent of <code>tar -tf</code> ). Otherwise extract the files (the equivalent of <code>tar -xf</code> ).                                                                                                                                                                                                                 |
| exdir         | The directory to extract files to (the equivalent of <code>tar -C</code> ). It will be created if necessary.                                                                                                                                                                                                                                              |
| compressed    | logical or character string. Values "gzip", "bzip2" and "xz" select that form of compression (and may be abbreviated to the first letter). TRUE indicates gzip compression, FALSE no known compression (but an external tar command may detect compression automatically), and NA (the default) indicates that the type is inferred from the file header. |
| extras        | NULL or a character string: further command-line flags such as '-p' to be passed to an external tar program.                                                                                                                                                                                                                                              |
| verbose       | logical: if true echo the command used.                                                                                                                                                                                                                                                                                                                   |
| restore_times | logical. If true (default) restore file modification times. If false, the equivalent of the '-m' flag. Times in tarballs are supposed to be in UTC, but tarballs have been submitted to CRAN with times in the future or far past: this argument allows such times to be discarded.                                                                       |
| tar           | character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted – but tar can also contain flags separated from the command by spaces.                                                                                                                                                                  |

## Details

This is either a wrapper for a tar command or for an internal implementation written in R. The latter is used if tarfile is a connection or if the argument tar is "internal" or "" (except on Windows, when tar.exe is tried first).

What options are supported will depend on the tar used. Modern GNU flavours of tar will support compressed archives, and since 1.15 are able to detect the type of compression automatically: version 1.20 added support for lzma and version 1.22 for xz compression using LZMA2. OS X 10.6 and later (and FreeBSD and some other OSes) have a tar (also known as bsdtar) from the 'libarchive' project which can also detect gzip and bzip2 compression automatically. For other flavours of tar, environment variable R\_GZIPCMD gives the command to decompress gzip and compress files, and R\_BZIPCMD for bzip2 files.

Arguments compressed, extras and verbose are only used when an external tar is used.

The internal implementation restores symbolic links as links on a Unix-alike, and as file copies on Windows (which works only for existing files, not for directories), and hard links as links. If the linking operation fails (as it may on a FAT file system), a file copy is tried. Since it uses [gzfile](#) to read a file it can handle files compressed by any of the methods that function can handle: at least compress, gzip, bzip2 and xz compression, and some types of lzma compression. It does not guard against restoring absolute file paths, as some tar implementations do. It will create the parent directories for directories or files in the archive if necessary. It handles the standard (USTAR/POSIX), GNU and pax ways of handling file paths of more than 100 bytes, and the GNU way of handling link targets of more than 100 bytes.

You may see warnings from the internal implementation such as

```
unsupported entry type 'x'
```

This often indicates an invalid archive: entry types "A-Z" are allowed as extensions, but other types are reserved. The only thing you can do with such an archive is to find a tar program that handles it, and look carefully at the resulting files. There may also be the warning

```
using pax extended headers
```

This indicates that additional information may have been discarded, such as ACLs, encodings ....

The standards only support ASCII filenames (indeed, only alphanumeric plus period, underscore and hyphen). `untar` makes no attempt to map filenames to those acceptable on the current system, and treats the filenames in the archive as applicable without any re-encoding in the current locale.

## Value

If `list = TRUE`, a character vector of (relative or absolute) paths of files contained in the tar archive.

Otherwise the return code from [system](#) with an external tar or 0L, invisibly.

| unzip | <i>Extract or List Zip Archives</i> |
|-------|-------------------------------------|

---

**Description**

Extract files from or list a zip archive.

**Usage**

```
unzip(zipfile, files = NULL, list = FALSE, overwrite = TRUE,
      junkpaths = FALSE, exdir = ".", unzip = "internal",
      setTimes = FALSE)
```

**Arguments**

|           |                                                                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| zipfile   | The pathname of the zip file: tilde expansion (see <a href="#">path.expand</a> ) will be performed.                                                               |
| files     | A character vector of recorded filepaths to be extracted: the default is to extract all files.                                                                    |
| list      | If TRUE, list the files and extract none. The equivalent of <code>unzip -l</code> .                                                                               |
| overwrite | If TRUE, overwrite existing files, otherwise ignore such files. The equivalent of <code>unzip -o</code> .                                                         |
| junkpaths | If TRUE, use only the basename of the stored filepath when extracting. The equivalent of <code>unzip -j</code> .                                                  |
| exdir     | The directory to extract files to (the equivalent of <code>unzip -d</code> ). It will be created if necessary.                                                    |
| unzip     | The method to be used. An alternative is to use <code>getOption("unzip")</code> , which on a Unix-alike may be set to the path to a unzip program.                |
| setTimes  | logical. For the internal method only, should the file times be set based on the times in the zip file? (NB: this applies to included files, not to directories.) |

**Value**

If `list = TRUE`, a data frame with columns `Name` (character) `Length` (the size of the uncompressed file, numeric) and `Date` (of class "[POSIXct](#)").

Otherwise for the "internal" method, a character vector of the filepaths extracted to, invisibly.

**Note**

The default internal method is a minimal implementation, principally designed for Windows' users to be able to unpack Windows binary packages without external software. It does not (for example) support Unicode filenames as introduced in zip 3.0: for that use `unzip = "unzip"` with `unzip 6.00` or later. It does have some support for bzip2 compression and > 2GB zip files (but not >= 4GB files pre-compression contained in a zip file: like many builds of unzip it may truncate these, in R's case with a warning if possible).

If unzip specifies a program, the format of the dates listed with `list = TRUE` is unknown (on Windows it can even depend on the current locale) and the return values could be NA or expressed in the wrong time zone or misinterpreted (the latter being far less likely as from unzip 6.00).

File times in zip files are stored in the style of MS-DOS, as local times to an accuracy of 2 seconds. This is not very useful when transferring zip files between machines (even across continents), so we chose not to restore them by default.

### Source

The internal C code uses zlib and is in particular based on the contributed ‘minizip’ application in the zlib sources (from <http://zlib.net>) by Gilles Vollant.

---

update.packages

*Compare Installed Packages with CRAN-like Repositories*

---

### Description

`old.packages` indicates packages which have a (suitable) later version on the repositories whereas `update.packages` offers to download and install such packages.

`new.packages` looks for (suitable) packages on the repositories that are not already installed, and optionally offers them for installation.

### Usage

```
update.packages(lib.loc = NULL, repos = getOption("repos"),
               contriburl = contrib.url(repos, type),
               method, instlib = NULL,
               ask = TRUE, available = NULL,
               oldPkgs = NULL, ..., checkBuilt = FALSE,
               type = getOption("pkgType"))
```

```
old.packages(lib.loc = NULL, repos = getOption("repos"),
            contriburl = contrib.url(repos, type),
            instPkgs = installed.packages(lib.loc = lib.loc),
            method, available = NULL, checkBuilt = FALSE,
            type = getOption("pkgType"))
```

```
new.packages(lib.loc = NULL, repos = getOption("repos"),
            contriburl = contrib.url(repos, type),
            instPkgs = installed.packages(lib.loc = lib.loc),
            method, available = NULL, ask = FALSE, ...,
            type = getOption("pkgType"))
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>lib.loc</code>    | character vector describing the location of R library trees to search through (and update packages therein), or NULL for all known trees (see <a href="#">.libPaths</a> ).                                                                                                                                                                                                                                    |
| <code>repos</code>      | character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as "http://cran.us.r-project.org".                                                                                                                                                                                                                                                                          |
| <code>contriburl</code> | URL(s) of the contrib sections of the repositories. Use this argument if your repository is incomplete. Overrides argument <code>repos</code> . Incompatible with <code>type = "both"</code> .                                                                                                                                                                                                                |
| <code>method</code>     | Download method, see <a href="#">download.file</a> . Unused if a non-NULL available is supplied.                                                                                                                                                                                                                                                                                                              |
| <code>instlib</code>    | character string giving the library directory where to install the packages.                                                                                                                                                                                                                                                                                                                                  |
| <code>ask</code>        | logical indicating whether to ask the user to select packages before they are downloaded and installed, or the character string "graphics", which brings up a widget to allow the user to (de-)select from the list of packages which could be updated. (The latter value only works on systems with a GUI version of <a href="#">select.list</a> , and is otherwise equivalent to <code>ask = TRUE</code> .) |
| <code>available</code>  | an object as returned by <a href="#">available.packages</a> listing packages available at the repositories, or NULL which makes an internal call to <a href="#">available.packages</a> . Incompatible with <code>type = "both"</code> .                                                                                                                                                                       |
| <code>checkBuilt</code> | If TRUE, a package built under an earlier major.minor version of R (e.g., 3.1) is considered to be 'old'.                                                                                                                                                                                                                                                                                                     |
| <code>oldPkgs</code>    | if specified as non-NULL, <code>update.packages()</code> only considers these packages for updating. This may be a character vector of package names or a matrix as returned by <code>old.packages</code> .                                                                                                                                                                                                   |
| <code>instPkgs</code>   | by default all installed packages, <a href="#">installed.packages</a> ( <code>lib.loc = lib.loc</code> ). A subset can be specified; currently this must be in the same (character matrix) format as returned by <code>installed.packages()</code> .                                                                                                                                                          |
| <code>...</code>        | Arguments such as <code>destdir</code> and dependencies to be passed to <a href="#">install.packages</a> .                                                                                                                                                                                                                                                                                                    |
| <code>type</code>       | character, indicating the type of package to download and install. See <a href="#">install.packages</a> .                                                                                                                                                                                                                                                                                                     |

**Details**

`old.packages` compares the information from [available.packages](#) with that from `instPkgs` (computed by [installed.packages](#) by default) and reports installed packages that have newer versions on the repositories or, if `checkBuilt = TRUE`, that were built under an earlier minor version of R (for example built under 3.1.x when running R 3.2.0). (For binary package types here is no check that the version on the repository was built under the current minor version of R, but it is advertised as being suitable for this version.)

`new.packages` does the same comparison but reports uninstalled packages that are available at the repositories. If `ask != FALSE` it asks which packages should be installed in the first element of `lib.loc`.

The main function of the set is `update.packages`. First a list of all packages found in `lib.loc` is created and compared with those available at the repositories. If `ask = TRUE` (the default) packages

with a newer version are reported and for each one the user can specify if it should be updated. If so the packages are downloaded from the repositories and installed in the respective library path (or instlib if specified).

For how the list of suitable available packages is determined see [available.packages](#). `available = NULL` make a call to `available.packages(contriburl = contriburl, method = method)` and hence by default filters on R version, OS type and removes duplicates.

### Value

`update.packages` returns `NULL` invisibly.

For `old.packages`, `NULL` or a matrix with one row per package, row names the package names and column names "Package", "LibPath", "Installed" (the version), "Built" (the version built under), "ReposVer" and "Repository".

For `new.packages` a character vector of package names, *after* any selected *via* ask have been installed.

### Warning

Take care when using dependencies (passed to [install.packages](#)) with `update.packages`, for it is unclear where new dependencies should be installed. The current implementation will only allow it if all the packages to be updated are in a single library, when that library will be used.

---

url.show

*Display a text URL*

---

### Description

Extension of [file.show](#) to display text files from a remote server.

### Usage

```
url.show(url, title = url, file = tempfile(),
         delete.file = TRUE, method, ...)
```

**Arguments**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>url</code>         | The URL to read from.                                   |
| <code>title</code>       | Title for the browser.                                  |
| <code>file</code>        | File to copy to.                                        |
| <code>delete.file</code> | Delete the file afterwards?                             |
| <code>method</code>      | File transfer method: see <a href="#">download.file</a> |
| <code>...</code>         | Arguments to pass to <a href="#">file.show</a> .        |

**Note**

Since this is for text files, it will convert to CRLF line endings on Windows.

**See Also**

[url](#), [file.show](#), [download.file](#)

**Examples**

```
## Not run: url.show("http://lib.stat.cmu.edu/datasets/csb/ch3a.txt")
```

---

|           |                                         |
|-----------|-----------------------------------------|
| URLencode | <i>Encode or Decode a (partial) URL</i> |
|-----------|-----------------------------------------|

---

**Description**

Functions to percent-encode or decode characters in URLs.

**Usage**

```
URLencode(URL, reserved = FALSE, repeated = FALSE)
URLdecode(URL)
```

**Arguments**

|                       |                                                                   |
|-----------------------|-------------------------------------------------------------------|
| <code>URL</code>      | a character string.                                               |
| <code>reserved</code> | logical: should ‘reserved’ characters be encoded? See ‘Details’.  |
| <code>repeated</code> | logical: should apparently already-encoded URLs be encoded again? |

## Details

Characters in a URL other than the English alphanumeric characters and ‘- \_ . ~’ should be encoded as % plus a two-digit hexadecimal representation, and any single-byte character can be so encoded. (Multi-byte characters are encoded byte-by-byte.) The standard refers to this as ‘percent-encoding’.

In addition, ‘! \$ & ' ( ) \* + , ; = : / ? @ # [ ]’ are reserved characters, and should be encoded unless used in their reserved sense, which is scheme specific. The default in `URLencode` is to leave them alone, which is appropriate for ‘file://’ URLs, but probably not for ‘http://’ ones.

An ‘apparently already-encoded URL’ is one containing %xx for two hexadecimal digits.

## Value

A character string.

## References

Internet STD 66 (formerly RFC 3986), <https://tools.ietf.org/html/std66>

## Examples

```
(y <- URLencode("a url with spaces and / and @"))
URLdecode(y)
(y <- URLencode("a url with spaces and / and @", reserved = TRUE))
URLdecode(y)

URLdecode(z <- "ab%20cd")
c(URLencode(z), URLencode(z, repeated = TRUE)) # first is usually wanted
```

---

**View***Invoke a Data Viewer*

---

**Description**

Invoke a spreadsheet-style data viewer on a matrix-like R object.

**Usage**

```
View(x, title)
```

**Arguments**

|                    |                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------|
| <code>x</code>     | an R object which can be coerced to a data frame with non-zero numbers of rows and columns.  |
| <code>title</code> | title for viewer window. Defaults to name of <code>x</code> prefixed by <code>Data:</code> . |

**Details**

Object `x` is coerced (if possible) to a data frame, then columns are converted to character using [format.data.frame](#). The object is then viewed in a spreadsheet-like data viewer, a read-only version of [data.entry](#).

If there are row names on the data frame that are not `1:nrow`, they are displayed in a separate first column called `row.names`.

Objects with zero columns or zero rows are not accepted.

The array of cells can be navigated by the cursor keys and Home, End, Page Up and Page Down (where supported by X11) as well as Enter and Tab.

**Value**

Invisible NULL. The functions puts up a window and returns immediately: the window can be closed via its controls or menus.

**See Also**

[edit.data.frame](#), [data.entry](#).

vignette

*View or List Package Vignettes***Description**

View a specified package vignette, or list the available ones.

**Usage**

```
vignette(topic, package = NULL, lib.loc = NULL, all = TRUE)

## S3 method for class 'vignette'
print(x, ...)
## S3 method for class 'vignette'
edit(name, ...)
```

**Arguments**

|                      |                                                                                                                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>topic</code>   | a character string giving the (base) name of the vignette to view. If omitted, all vignettes from all installed packages are listed.                                            |
| <code>package</code> | a character vector with the names of packages to search through, or <code>NULL</code> in which ‘all’ packages (as defined by argument <code>all</code> ) are searched.          |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known.               |
| <code>all</code>     | logical; if <code>TRUE</code> search all available packages in the library trees specified by <code>lib.loc</code> , and if <code>FALSE</code> , search only attached packages. |
| <code>x, name</code> | Object of class <code>vignette</code> .                                                                                                                                         |
| <code>...</code>     | Ignored by the <code>print</code> method, passed on to <code>file.edit</code> by the <code>edit</code> method.                                                                  |

**Details**

Function `vignette` returns an object of the same class, the `print` method opens a viewer for it. The program specified by the `pdfviewer` option is used for viewing PDF versions of vignettes. If several vignettes have PDF/HTML versions with base name identical to `topic`, the first one found is used.

If no topics are given, all available vignettes are listed. The corresponding information is returned in an object of class `"packageIQR"`.

The `edit` method copies the R code extracted from the vignette to a temporary file and opens the file in an editor (see [edit](#)). This makes it very easy to execute the commands line by line, modify them in any way you want to help you test variants, etc.

**See Also**

[browseVignettes](#) for an HTML-based vignette browser; `RShowDoc(<basename>, package = "<pkg>")` displays a “rendered” vignette (pdf or html).

## Examples

```
## List vignettes from all *attached* packages
vignette(all = FALSE)

## List vignettes from all *installed* packages (can take a long time!):
vignette(all = TRUE)

## Not run:
## Open the grid intro vignette
vignette("grid")

## The same
v1 <- vignette("grid")
print(v1)

## Now let us have a closer look at the code
edit(v1)

## An alternative way of extracting the code,
## R file is written to current working directory
Stangle(v1$file)

## A package can have more than one vignette (package grid has several):
vignette(package = "grid")
vignette("rotated")
## The same, but without searching for it:
vignette("rotated", package = "grid")

## End(Not run)
```

---

write.table

*Data Output*

---

## Description

write.table prints its required argument x (after converting it to a data frame if it is not one nor a matrix) to a file or [connection](#).

## Usage

```
write.table(x, file = "", append = FALSE, quote = TRUE, sep = " ",
            eol = "\n", na = "NA", dec = ".", row.names = TRUE,
            col.names = TRUE, qmethod = c("escape", "double"),
            fileEncoding = "")

write.csv(...)
write.csv2(...)
```

**Arguments**

|              |                                                                                                                                                                                                                                                                                                                                                            |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x            | the object to be written, preferably a matrix or data frame. If not, it is attempted to coerce x to a data frame.                                                                                                                                                                                                                                          |
| file         | either a character string naming a file or a <a href="#">connection</a> open for writing. "" indicates output to the console.                                                                                                                                                                                                                              |
| append       | logical. Only relevant if file is a character string. If TRUE, the output is appended to the file. If FALSE, any existing file of the name is destroyed.                                                                                                                                                                                                   |
| quote        | a logical value (TRUE or FALSE) or a numeric vector. If TRUE, any character or factor columns will be surrounded by double quotes. If a numeric vector, its elements are taken as the indices of columns to quote. In both cases, row and column names are quoted if they are written. If FALSE, nothing is quoted.                                        |
| sep          | the field separator string. Values within each row of x are separated by this string.                                                                                                                                                                                                                                                                      |
| eol          | the character(s) to print at the end of each line (row). For example, eol = "\r\n" will produce Windows' line endings on a Unix-alike OS, and eol = "\r" will produce files as expected by Excel:mac 2004.                                                                                                                                                 |
| na           | the string to use for missing values in the data.                                                                                                                                                                                                                                                                                                          |
| dec          | the string to use for decimal points in numeric or complex columns: must be a single character.                                                                                                                                                                                                                                                            |
| row.names    | either a logical value indicating whether the row names of x are to be written along with x, or a character vector of row names to be written.                                                                                                                                                                                                             |
| col.names    | either a logical value indicating whether the column names of x are to be written along with x, or a character vector of column names to be written. See the section on 'CSV files' for the meaning of col.names = NA.                                                                                                                                     |
| qmethod      | a character string specifying how to deal with embedded double quote characters when quoting strings. Must be one of "escape" (default for write.table), in which case the quote character is escaped in C style by a backslash, or "double" (default for write.csv and write.csv2), in which case it is doubled. You can specify just the initial letter. |
| fileEncoding | character string: if non-empty declares the encoding to be used on a file (not a connection) so the character data can be re-encoded as they are written. See <a href="#">file</a> .                                                                                                                                                                       |
| ...          | arguments to write.table: append, col.names, sep, dec and qmethod cannot be altered.                                                                                                                                                                                                                                                                       |

**Details**

If the table has no columns the rownames will be written only if row.names = TRUE, and *vice versa*.

Real and complex numbers are written to the maximal possible precision.

If a data frame has matrix-like columns these will be converted to multiple columns in the result (via [as.matrix](#)) and so a character col.names or a numeric quote should refer to the columns in the result, not the input. Such matrix-like columns are unquoted by default.

Any columns in a data frame which are lists or have a class (e.g., dates) will be converted by the appropriate as.character method: such columns are unquoted by default. On the other hand,

any class information for a matrix is discarded and non-atomic (e.g., list) matrices are coerced to character.

Only columns which have been converted to character will be quoted if specified by `quote`.

The `dec` argument only applies to columns that are not subject to conversion to character because they have a class or are part of a matrix-like column (or matrix), in particular to columns protected by `I()`. Use `options("OutDec")` to control such conversions.

In almost all cases the conversion of numeric quantities is governed by the option `"scipen"` (see `options`), but with the internal equivalent of `digits = 15`. For finer control, use `format` to make a character matrix/data frame, and call `write.table` on that.

These functions check for a user interrupt every 1000 lines of output.

If `file` is a non-open connection, an attempt is made to open it and then close it after use.

To write a Unix-style file on Windows, use a binary connection e.g. `file = file("filename", "wb")`.

## CSV files

By default there is no column name for a column of row names. If `col.names = NA` and `row.names = TRUE` a blank column name is added, which is the convention used for CSV files to be read by spreadsheets. Note that such CSV files can be read in R by

```
read.csv(file = "<filename>", row.names = 1)
```

`write.csv` and `write.csv2` provide convenience wrappers for writing CSV files. They set `sep` and `dec` (see below), `qmethod = "double"`, and `col.names` to `NA` if `row.names = TRUE` (the default) and to `TRUE` otherwise.

`write.csv` uses `"."` for the decimal point and a comma for the separator.

`write.csv2` uses a comma for the decimal point and a semicolon for the separator, the Excel convention for CSV files in some Western European locales.

These wrappers are deliberately inflexible: they are designed to ensure that the correct conventions are used to write a valid file. Attempts to change `append`, `col.names`, `sep`, `dec` or `qmethod` are ignored, with a warning.

CSV files do not record an encoding, and this causes problems if they are not ASCII for many other applications. Windows Excel 2007/10 will open files (e.g., by the file association mechanism) correctly if they are ASCII or UTF-16 (use `fileEncoding = "UTF-16LE"`) or perhaps in the current Windows codepage (e.g., `"CP1252"`), but the 'Text Import Wizard' (from the 'Data' tab) allows far more choice of encodings. Excel:mac 2004/8 can *import* only 'Macintosh' (which seems to mean Mac Roman), 'Windows' (perhaps Latin-1) and 'PC-8' files. OpenOffice 3.x asks for the character set when opening the file.

There is an IETF RFC4180 (<https://tools.ietf.org/html/rfc4180>) for CSV files, which mandates comma as the separator and CRLF line endings. `write.csv` writes compliant files on Windows: use `eol = "\r\n"` on other platforms.

## Note

`write.table` can be slow for data frames with large numbers (hundreds or more) of columns: this is inevitable as each column could be of a different class and so must be handled separately. If they are all of the same class, consider using a matrix instead.

**See Also**

The ‘R Data Import/Export’ manual.

[read.table](#), [write](#).

[write.matrix](#) in package **MASS**.

**Examples**

```
## Not run:
## To write a CSV file for input to Excel one might use
x <- data.frame(a = I("a \" quote"), b = pi)
write.table(x, file = "foo.csv", sep = ",", col.names = NA,
            qmethod = "double")
## and to read this file back into R one needs
read.table("foo.csv", header = TRUE, sep = ",", row.names = 1)
## NB: you do need to specify a separator if qmethod = "double".

### Alternatively
write.csv(x, file = "foo.csv")
read.csv("foo.csv", row.names = 1)
## or without row names
write.csv(x, file = "foo.csv", row.names = FALSE)
read.csv("foo.csv")

## To write a file in Mac Roman for simple use in Mac Excel 2004/8
write.csv(x, file = "foo.csv", fileEncoding = "macroman")
## or for Windows Excel 2007/10
write.csv(x, file = "foo.csv", fileEncoding = "UTF-16LE")

## End(Not run)
```

---

zip

---

*Create Zip archives*

---

**Description**

A wrapper for an external zip command to create zip archives.

**Usage**

```
zip(zipfile, files, flags = "-r9X", extras = "",
    zip = Sys.getenv("R_ZIPCMD", "zip"))
```

**Arguments**

|         |                                                                                                     |
|---------|-----------------------------------------------------------------------------------------------------|
| zipfile | The pathname of the zip file: tilde expansion (see <a href="#">path.expand</a> ) will be performed. |
| files   | A character vector of recorded filepaths to be included.                                            |

|        |                                                                         |
|--------|-------------------------------------------------------------------------|
| flags  | A character string of flags to be passed to the command: see 'Details'. |
| extras | An optional character vector: see 'Details'.                            |
| zip    | A character string specifying the external command to be used.          |

**Details**

On a Unix-alike, the default for zip will by default use the value of R\_ZIPCMD, which is set in 'etc/Renviron' if an unzip command was found during configuration. On Windows, the default relies on a zip program (for example that from Rtools) being in the path.

The default for flags is that appropriate for zipping up a directory tree in a portable way: see the system-specific help for the zip command for other possibilities.

Argument extras can be used to specify -x or -i followed by a list of filepaths to exclude or include.

**Value**

The status value returned by the external command, invisibly.
